G12 Driver Assistance Systems
General information

Symbols used

The following symbol is used in this document to facilitate better comprehension or to draw attention to very important information:

⚠️

Contains important safety information and information that needs to be observed strictly in order to guarantee the smooth operation of the system.

Information status and national-market versions

BMW Group vehicles meet the requirements of the highest safety and quality standards. Changes in requirements for environmental protection, customer benefits and design render necessary continuous development of systems and components. Consequently, there may be discrepancies between the contents of this document and the vehicles available in the training course.

This document basically relates to the European version of left hand drive vehicles. Some operating elements or components are arranged differently in right-hand drive vehicles than shown in the graphics in this document. Further differences may arise as the result of the equipment specification in specific markets or countries.

Additional sources of information

Further information on the individual topics can be found in the following:

- Owner's Handbook
- Integrated Service Technical Application.

G12 Driver Assistance Systems

1. Introduction

The range of existing assistance systems has been expanded in the G12 to include new innovative systems. The interplay between the varied and intelligent assistance systems supports the driver in every respect; from making driving more comfortable to providing the reassuring feeling of safety on all roads.

The assistance systems help to make the driver's life easier by:

- providing the driver with information
- prompting the driver with suggestions
- automatically intervening in the driving process

This information bulletin contains an overview of all the assistance systems used in the G12:

- Camera-based collision warning
- Collision warning with city braking function
- Pedestrian warning with city braking function
- Road sign recognition
- Proactive Active Driving Assistant
- Lane departure warning
- Blind spot detection
- Side collision warning
- Alertness assistant
- Night vision
- Camera systems
- cross-traffic warning
- Park Distance Control
- Parking Maneuver Assistant
- Speed control
- Speed limit warning
- Steering and lane control assistant including traffic jam assistant
- Active Lane keeping assistant with active side collision protection

Identifying road users driving ahead as well as detecting objects and lane edges are among the most important prerequisites for the assistance systems. This applies not only for the far range but also the close range.

The optional functions available for the G12 are implemented either as camera-based systems with a shared camera and integrated control unit, or as sensor systems such as ultrasonic or radar sensors. Evaluation signals provided by various control units (for example, from the Advanced Crash Safety Module (ACSM)) are also taken into consideration.

For more information on the operating concept of the assistance systems, please refer to the Owner's Handbook.

</table>
As the requirements placed on the KAFAS camera have increased in the G12, the existing monochrome camera has been replaced by a stereo camera.

The KAFAS stereo camera is composed of two high-resolution CMOS monochrome cameras, which are installed in a housing with approximately 20 cm between them. The KAFAS stereo camera housing now also serves as an equipment holder for the KAFAS control unit, which has more powerful processors.

CMOS cameras are characterized by their low power consumption, compact size and very high frame rate.

**CMOS = Complementary Metal Oxide Semiconductor**

The KAFAS stereo camera is calibrated within a distance of approximately 2 km during driving. The KAFAS stereo camera is the key element of the following systems:
3. KAFAS

- Tailgate warning
- Collision warning with city braking function
- Pedestrian warning with city braking function
- Lane departure warning
- Road sign recognition.

The KAFAS stereo camera plays a supporting role in the following systems:

- Active Cruise Control with Stop&Go (ACC)
- Steering and lane control assistant including traffic jam assistant
- Active lane keeping assistant with active side collision protection

3.1. Detection range

Due to differences in perspective between the left and right optical path of the camera, the stereo camera is able to measure the distance to an object and now also its height above road level.

While the monochrome camera merely estimates distances, the stereo camera can determine the distance to an object fairly accurately – to within approximately 20 to 30 cm – from approximately 40 m away.
G12 Driver Assistance Systems

3. KAFAS

In principle, the evaluation electronics in the KAFAS stereo camera use the same effect as is used in a human to create spatial vision. This is known as the parallax shift between two images.

The KAFAS stereo camera not only enables the position of an object to be determined, but also its movement and direction of movement. For every pixel of a detected object, the direction of movement on the horizontal, vertical and longitudinal axis can be determined.

The KAFAS stereo camera has a detection range of up to approximately 40 m ahead of the vehicle and up to approximately 5 m in front of the vehicle on the right and left. The overall detection range of the KAFAS stereo camera is approximately 500 m.

3.2. Person recognition

The KAFAS stereo camera captures the scene in front of the vehicle and detects entire rear views of moving and stationary vehicles in the field of view using image processing. The KAFAS stereo camera also ensures that driving lane information, vehicle positions and movements are determined at the same time.

With the aid of the image data from the KAFAS stereo camera, objects can be clearly identified as vehicles and their transverse movements as lane changes. The KAFAS stereo camera also detects people and cyclists.

Example of pedestrian recognition by the KAFAS stereo camera: pedestrian approaching from the side steps into the road and is partially hidden

The two separate optical paths are also beneficial in challenging conditions, for example difficult lighting conditions, where there is low contrast between the image and background or when several objects are closely lined up one after the other.

Thanks to the redundant image detection of the stereo camera, it is now possible to reliably detect obstacles and determine their size from a single image.
3.3. Road sign recognition

The KAFAS stereo camera is also responsible for detecting top speed limitation road signs. The detection of no overtaking/overtaking permitted signs or markings is also implemented in the G12.

3.4. Lane detection

The KAFAS stereo camera installed in the mirror base of the interior mirror on the windshield monitors the area in front of the vehicle.

The KAFAS stereo camera records the roadway up to approximately 40 m ahead of the vehicle and up to approximately 5 m to the right and left of the vehicle. The image data is then evaluated by the KAFAS control unit integrated in the KAFAS stereo camera. Using image processing, the control unit searches the images recorded by the KAFAS stereo camera for lane and road markings.

The appearance of the road markings can vary considerably in the image depending on the country, type of road or the current ambient conditions. The system can detect a wide range of road markings and types of markings. For a lane marking to be evaluated, the KAFAS stereo camera and the KAFAS control unit must first be able to clearly identify it. A lane must also have an average width greater than 2.5 m for it to be evaluated.
G12 Driver Assistance Systems

3. KAFAS

3.5. Detection of the road condition

The KAFAS stereo camera in the G12 also detects the road condition.

In vehicles with the Executive Drive Pro optional equipment (OE 2VS), the data collected is used to adapt the chassis and suspension setting to the road condition by changing various setting parameters in the Dynamic Drive (ARS) and Electronic Damper Control (EDC) and tailoring the interaction with the two-axle air suspension.

Detection of road bumps with the help of the stereo camera

Objects can now be dealt with actively instead of reactively, and therefore more easily, at speeds of approximately 15 to 100 km/h.

The structure of the vehicle moves less vertically, as the vehicle drives in harmony with the road. Bumps are less noticeable for the driver.

3.6. Functional limitations

The function of the KAFAS stereo camera and thus the function of the corresponding assistance systems may be impaired due to the physical limits of the optical systems, for example in the following situations:

- Heavy fog, rain, spray or snow
- Strong light in the camera lens
- If the field of view of the KAFAS stereo camera or the windscreen is dirty
- On tight bends
- If boundary lines are missing, worn, poorly visible, converging or diverging, or not clearly recognizable, as may be the case when roadworks are being carried out
- If boundary lines are covered by snow, ice, dirt or water
- If boundary lines are covered by objects
G12 Driver Assistance Systems

3. KAFAS

- If driving at close proximity to a vehicle driving ahead
- If the windscreen in front of the interior mirror is misted over, soiled or covered by stickers, e.g. tax discs, etc.
- Up to 10 seconds after driving readiness is activated via the start/stop button
- During the calibration process for the KAFAS stereo camera immediately after vehicle delivery or a camera change

Example of limits of the KAFAS stereo camera

⚠️

Due to functional limitations and system restrictions it may transpire that warnings and orders are not issued, are issued too late or are unwarranted. Therefore, be attentive in order to be able to actively intervene at any time. Otherwise, there is a risk of an accident.
The familiar optional equipment system (SAS) control unit is also used in the G12 and provides a range of driver assistance functions.

Possible functions:

- Tailgate warning
- Collision warning with city braking function
- Pedestrian warning with city braking function
- Dynamic Brake Control
- Distance information
- Dynamic Cruise Control
- Active speed control with Stop&Go function
- Lane & traffic jam assistant
- Speed limit
- Blind spot detection
- Lane departure warning
- Cross-traffic warning
- Parking Maneuver Assistant
- Proactive Active Driving Assistant
G12 Driver Assistance Systems

5. Overview Of Sensors

The graphic below provides an overview of the main sensors used in the G12 for the assistance systems and shows their installation locations.

</table>
Due to the ever increasing amount of traffic on our roads, assistance systems in vehicles continue to gain in importance. They assist the driver on highways, single-lane roads and in urban environments.

Urban traffic is just one area that presents an ever increasing number of challenges. Car drivers must be constantly aware of cyclists and pedestrians. Systems such as the pedestrian warning with city brake activation are helpful in this respect. Night Vision can assist the driver when driving on single-lane roads with adjacent woodland (deer crossings, etc.). The lane departure and Blind spot detection as well as the side collision warning provide even more safety in traffic. Accidents can be avoided through automatic brake interventions, active steering interventions or a combination of both.

Depending on the vehicle equipment, Intelligent Safety consists of one or several systems, which can help to avoid a potential collision. The following systems are offered in the G12:

- Tailgate warning with braking function
- Pedestrian warning with city braking function
- Night Vision with person and animal recognition
- Lane departure warning
- Blind spot detection
- Side collision warning

The Intelligent Safety button enables the assistance systems to be operated centrally. This means the systems can be switched on or off using a button and the submenu can be called up to personalize the settings.

G12 Driver Assistance Systems

6. Intelligent Safety

Press button

- The "Intelligent Safety" menu is displayed on the central information display (CID). Settings can be made using the controller. The individual settings are stored for the respective ID transmitter used.

Press and release button

- When all Intelligent Safety systems are switched on: Intelligent Safety systems are switched off individually depending on the individual setting.
- When all Intelligent Safety systems are not switched on: All Intelligent Safety systems are switched on.

Press button for an extended period

- All Intelligent Safety systems are switched off.

The Intelligent Safety systems are automatically active after each engine start via the START-STOP button.
6.1. Overview of the configuration menu

The system is operated by pressing the Intelligent Safety button and using a menu to configure the Intelligent Safety systems on the Central Information Display (CID).
# G12 Driver Assistance Systems

## 6. Intelligent Safety

### Index | Explanation
--- | ---
1 | "Intelligent Safety" configuration menu
2 | "ALL ON" selection
3 | "INDIVIDUAL" selection
4 | "Configure INDIVIDUAL"
5 | "ALL OFF" selection
6 | Note for the driver: in this example not all of the Intelligent Safety systems could be activated.
7 | Note for the driver: the colored circle shows the driver the activation status of the Intelligent Safety systems. The color of the circle changes always matches the color of the Intelligent Safety button indicator light.

### "ALL ON"
- All Intelligent Safety systems are switched on. The basic settings are activated for the sub-functions, for example the warning time setting. The Intelligent Safety button lights up green.

### "INDIVIDUAL"
- The Intelligent Safety systems are switched on in accordance with the individual settings. Depending on the vehicle equipment, the Intelligent Safety systems can be configured individually. The individual settings are activated and stored for the respective ID transmitter used.

6. Intelligent Safety

As soon as a setting is changed in the menu, all the settings the driver has previously configured are activated. The Intelligent Safety button lights up orange.

"ALL OFF"

- All Intelligent Safety systems are switched off. The Intelligent Safety button does not light up.
G12 Driver Assistance Systems

7. Collision Warning

The camera-based collision warning is part of the Active Driving Assistant optional equipment (OE 5AS) in the G12 and is implemented using the KAFAS stereo camera.

The collision warning in the new BMW 7 Series contains the familiar "Collision warning with city brake activation" and the "Pedestrian warning with city brake activation" functions.

In vehicles with the Active Cruise Control with Stop&Go function optional equipment (OE ZN7), the cruise control radar sensor is also used to control the collision warning.

Vehicles with the Active Driving Assistant Plus optional equipment (OE 5AT) have the Active Cruise Control with Stop&Go function optional equipment (OE ZN7) integrated as standard.

If the vehicle is not equipped with the Active Driving Assistant (OE 5AS) or Active Driving Assistant Plus (OE 5AT) optional equipment, but does have the Active Cruise Control with Stop&Go function optional equipment (OE ZN7), the customer also receives a collision warning. However, in this case the pedestrian warning is not included.

The system warns the driver in situations where a collision is imminent. The early warning, a visual signal, is issued first to draw the driver's attention to the situation. If the situation becomes more critical, an acute early warning in the form of a visual and acoustic signal is issued. The nature of the warning is such that the driver can still prevent a collision providing he acts quickly.

7.1. Functional principle

The KAFAS stereo camera captures the scene in front of the vehicle and detects entire rear views of moving and stationary vehicles in the field of view using image processing.

In vehicles with the Active Cruise Control with Stop&Go function optional equipment (OE ZN7), in addition to the KAFAS stereo camera image data, information from the radar sensor is also evaluated.
### G12 Driver Assistance Systems

#### 7. Collision Warning

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The corresponding warning stages "early warning" and "acute warning" are output in critical situations on the basis of the calculated positions, distances and relative speeds of other vehicles. For the early warning the brakes of the vehicle are prepared for emergency braking and the activation thresholds of the Dynamic Brake Control are reduced. If the driver makes the conscious decision to drive up close to the vehicle ahead, warnings which may otherwise be distracting can be prevented by reducing the sensitivity of the system.

#### 7.1.1. Collision warning with city braking function

The collision warning with city brake activation (City Collision Mitigation option OE ZN3) adds a brake activation function to the camera-based collision warning from a speed of roughly 5 km/h up to a maximum speed of 80 km/h. If there is still no response from the driver in this speed range after an acute warning is issued, the vehicle is decelerated at a maximum rate of 4 m/s².

Example of vehicle identification by KAFAS camera

<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Vehicle in same lane</td>
</tr>
<tr>
<td>2</td>
<td>Vehicle in different lane</td>
</tr>
</tbody>
</table>

The duration of the brake intervention is limited to approximately 1.5 seconds. Additional dangers for the traffic behind are therefore avoided.
G12 Driver Assistance Systems

7. Collision Warning

7.1.2. Pedestrian warning with city braking function

The pedestrian warning with city braking function (Daytime pedestrian detection OE ZN2) is designed to prevent possible collisions with pedestrians in urban areas or reduce the effects of an accident. The system warns of a possible collision with pedestrians from a speed of approximately 10 km/h up to a maximum speed of 60 km/h and assists the driver with a brake intervention shortly before a collision.

The KAFAS stereo camera captures the scene in front of the vehicle and detects pedestrians in the field of view using image processing.

![Example of person recognition by KAFAS camera](image)

Based on the calculated positions, distances and the movement of the detected pedestrians, an acute warning is issued in critical situations. An early warning is not available for the pedestrian warning with city braking function (OE ZN2).

With an acute warning the vehicle is decelerated by roughly 4 m/s². The duration of the brake intervention is limited to approximately 1.5 seconds. Additional dangers for the traffic behind are therefore avoided.

7.2. Warning and braking function

The operating principle of the collision warning is based on a detection and warning algorithm. Machine vision detects pedestrians and vehicles in the detection range of the camera. If there is a risk of a collision, a warning symbol is shown in the instrument cluster (KOMBI), or in the Head-Up Display for vehicles with the Head-Up Display standard equipment (OE 610). The warning function is divided into two stages. The next probable movement of an object is determined based on the current movement of the detected object and, taking into account the movement of the object, a collision risk is identified. If a situation is evaluated as critical by the warning algorithm, a warning is issued and braking is introduced based on a multistage warning concept. The warnings and brake interventions differ for pedestrians and vehicles.
7. Collision Warning

7.2.1. Displays

<table>
<thead>
<tr>

  - Request for intervention by braking and evasive action, if required |
| ![Person Symbol] | **Acute warning:**  
  - Person symbol flashes red and a signal sounds  
  - Request for intervention by braking and evasive action, if required |

7.2.2. Early warning

Occasions when an early warning is issued include when there is a collision risk because the vehicle driving ahead is being driven at a much slower speed and/or if the distance to a driven or stationary vehicle ahead is extremely short.

An early warning is indicated by a vehicle symbol which lights up red in the instrument cluster (KOMBI) or Head-Up Display. The early warning is only issued for vehicles and not for pedestrians.

The point at which the early warning is issued can be configured in the "Intelligent Safety systems“ menu on the central information display (CID).

⚠️

The collision warning is dependent on the vehicle's own driving speed. The distance measured for the collision warning is significantly lower than the legally required minimum distance. It is therefore the responsibility of the driver to adhere to the legal minimum distance.

7.2.3. Acute warning

The acute warning is issued by the system as late as possible and only if there is an imminent danger of a collision when the vehicle is approaching the vehicle driving ahead at a relatively high differential speed or if there is an imminent danger of a collision with a pedestrian. The time of the acute warning is measured so that a collision can only be avoided by immediate emergency braking or by swerving. The acute warning therefore cannot be deliberately brought about or monitored by the driver. The acute warning is issued for vehicles and pedestrians.
G12 Driver Assistance Systems

7. Collision Warning

If the vehicle is approaching the vehicle driving ahead or a pedestrian at a very low speed, an acute warning is not issued even when the distance is very small. This intentional driving situation only triggers the early warning. This way there are fewer meaningless and annoying acute warnings issued by the system.

The acute warning cannot be deactivated separately. The timing of the acute warning also cannot be adjusted. If the acute warning is not to be issued, the "collision warning" front protective function must be deactivated.

If an acute warning is issued, this is indicated to the driver by a red flashing vehicle symbol or a red flashing person symbol in the instrument cluster (KOMBI) or Head-Up Display. In addition, an acoustic warning signal is sounded.

The acute warning for pedestrians is issued within a speed range of approximately 10 km/h to 60 km/h. The acute warning for vehicles is issued at speeds above approximately 5 km/h.

When the acute warning is issued, the brake system is also preconditioned in order to achieve quicker and sharper deceleration. With these measures the driver also receives specific support at the same time as the warning in order to be able to respond effectively.

⚠️

The acute warning does not relieve the driver of his responsibility to adapt the speed and driving style to the traffic conditions.

7.2.4. Brake intervention

With the camera based, collision warning with city collision mitigation (OE ZN3 included with OE 5AS); If the driver no longer has the option to avoid the accident with his own response, automatic brake intervention is effected as a last step. The brake intervention is effected at a brake force of about 4 m/s² (camera based) and can have the effect of avoiding a collision up to a differential speed of about 18 km/h. At higher differential speeds the impact speed is reduced by a smaller amount. Just like the driver can support the effect of the system, he also has the option of overriding and thus cancelling the automatic panic braking at any time with a steering wheel movement (avoidance maneuver), by accelerating or with a sharp brake intervention.

With the camera and radar based, collision warning system (included with OE 5AT); If the driver no longer has the option to avoid the accident with his own response, automatic brake intervention is effected as a last step. The brake intervention is effected at a brake force of about 8 m/s² (camera/radar based) and can have the effect of avoiding a collision up to a differential speed (delta) of about 30 km/h.

Therefore, both systems can bring car to a stop, the difference is that you are more likely to see this happen in a 5AT car then a 5AS car. This is why 5AS is referred to as “city collision MITIGATION” because this is the more likely use case as opposed to “AVOIDANCE” with 5AT.

The brake intervention is effected for pedestrians in the speed range between 10 and 60 km/h and for vehicles in the speed range between 5 and 60 km/h.

For a brake intervention to be possible, the Dynamic Stability Control (DSC) must be switched on.
Time plan for collision warning with city braking function (OE ZN3)

The time plan of the warnings and braking is demonstrated in the following graphic. If an avoidance measure by the driver is detected, there is no brake intervention.

7.4. Limits of the system

Range of detection

⚠️

The collision warning has a limited capacity for detection.

As a result, incorrect or delayed warnings may occur. It is possible the following vehicles are not detected:

- A slow vehicle when driving off at high speed
- Vehicles that suddenly swerve or decelerate rapidly
- Vehicles with an unusual rear view or with insufficiently visible rear lights
- Partially concealed vehicles
- Two-wheeled vehicles travelling ahead.

Functional limitations

The function of the KAFAS stereo camera and thus also the function of the corresponding assistance systems may be impaired in the following situations, for example:

- Heavy fog, rain, spray or snow
- Insufficient light
- Strong light in the camera lens
- If the field of view of the KAFAS stereo camera or the windscreen is dirty
- On sharp bends
- With pedestrians up to approximately 80 cm in height
- Up to 10 seconds after the engine start via the START-STOP button
- During the calibration process for the KAFAS stereo camera immediately after vehicle delivery or a camera change

⚠️

Due to functional limitations and system restrictions it may transpire that warnings and orders are not issued, are issued too late or are unwarranted. Therefore, be attentive in order to be able to actively intervene at any time. Otherwise, there is a risk of an accident.
G12 Driver Assistance Systems
8. Lane Departure Warning

The lane departure warning is an element of the optional equipment Active Driving Assistant (SA 5AS) and the optional equipment Active Driving Assistant Plus (SA 5AT).

The lane departure warning detects lane markings from a speed of approximately 70 km/h and warns the driver against unintentionally leaving the lane.

The information required about usable roadway and lane markings is provided by the KAFAS stereo camera. Based on the calculated positions, lane edges and curves in relation to the relative position of the driver’s vehicle, a corresponding warning is issued.

If the driver crosses the lane marking unintentionally (without using the turn indicator) or leaves the road boundary, he is warned by the steering wheel vibrating gently and has the opportunity to react accordingly. The vibration in the steering wheel can be compared to the vibration effect when driving over a profiled road marking.

In the settings menu the driver can set the desired strength of the vibration warning on the steering wheel via the iDrive.

<table>
<thead>
<tr>
<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Steering wheel vibration menu</td>

</tr>
<tr>
<td>4</td>
<td>&quot;Medium&quot;</td>
</tr>
<tr>
<td>5</td>
<td>&quot;Light&quot;</td>
</tr>
</tbody>
</table>

If the driver uses the turn indicator when moving across to another lane, the lane departure warning recognizes that this is an intentional lane change and a warning is not issued.

The lane departure warning can be configured individually in the Intelligent Safety system submenu.
8. Lane Departure Warning

The individual settings applied by the driver are saved for the driver profile currently in use.

</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Symbol" /></td>
<td>At least one lane boundary has been detected and warnings can be issued.</td>
</tr>
</tbody>
</table>
8.1. Active steering intervention

In vehicles with the side collision warning (included in Active Driving Assistant Plus optional equipment OE 5AT), the driver is assisted by another measure known as "active steering intervention".

If the driver does not react to the warning issued by the lane departure warning system and crosses the lane marking, he is assisted to stay in lane by a brief active steering intervention.

The active steering intervention can be felt on the steering wheel, but can be overridden by the driver at any time. If the driver does override the intervention, the active steering intervention is cancelled.

The "steering intervention" for the lane departure warning can be switched on and off in the iDrive menu in vehicles with the side collision warning by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Intelligent Safety"
- "Steering intervention"

The configuration menu can be accessed quickly by pressing the Intelligent Safety button.

8.3. Deactivation criteria

The lane departure warning is available at a speed range from 70 to 210 km/h.

A warning is not issued in the following situations:

- When the driver uses the turn indicator
- In roadworks
- When the lane width is less than 2.60 m

The warning is cancelled in the following situations:

- Automatically after approximately 3 seconds
- As soon as the driver moves back into his own lane
- If the turn indicator is used
- When sharp braking or steering maneuvers are made and when the Dynamic Stability Control (DSC) intervenes.

8.4. Limits of the system

The function of the system may not be available or may only be available to a limited extent in the following situations:

- heavy fog, rain or snow
- at sharp bends or on narrow roadways
- if boundary lines are covered by snow, ice, dirt or water
- if boundary lines are covered by objects
- if boundary lines are missing, worn, poorly visible, converging or diverging, or not clearly recognizable, such as when driving through roadworks

⚠️

The system does not replace the personal assessment of the road and the traffic situation. The lane departure warning is only intended to assist the driver. When active lane departure warnings are issued, the steering wheel should not be moved through any unnecessarily heavy-handed actions.
9. Blind Spot Detection

The Blind spot detection system can detect traffic situations that could pose a risk if the driver changes lane. These traffic situations include vehicles approaching quickly from behind or vehicles in the driver’s blind spot.

The driver may find it difficult to judge these situations, especially when it is dark. The radar sensors detect vehicles in the blind spot and work effectively regardless of the lighting conditions. In addition, they are able to reliably detect such situations up to a distance of approximately 70 m away and irrespective of the weather conditions.

When a vehicle is approaching quickly or moves into the blind spot of the driver’s vehicle, the system assists the driver by correctly judging the situation. If the lane next to the driver’s vehicle is occupied, the radar sensors detect the vehicles in the neighboring lane.

The control units (radar sensors) for the Blind spot detection (SWW) are located under the rear bumper.

The control unit for the Blind spot detection (SWW) (primary) is installed on the right and the control unit for the Blind spot detection (SWW2) (secondary) is installed on the left.

When a vehicle is detected and the system is activated, the driver is informed of the situation by an unobtrusive indicator in the exterior mirror. By having this information before making a lane change maneuver, the driver can confidently prepare for the lane change and avoid critical situations from
G12 Driver Assistance Systems

9. Blind Spot Detection

the outset.

The Blind spot detection indicators are located in the exterior mirror glass.

If the driver intends to make a lane change in what the system detects to be a critical situation, and demonstrates this intention by using the turn indicator, the second, more severe "warning" is issued. The corresponding indicator in the exterior mirror flashes with high intensity and the steering wheel starts to vibrate. This warns the driver using the exact operating element that he must use to make the dangerous situation safe. To avoid a potential collision, the driver must steer the vehicle back into his own lane.

The Blind spot detection can be configured individually in the Intelligent Safety system submenu.
9. Blind Spot Detection

9.1. Active steering intervention

Depending on the setting in the "Intelligent Safety" menu, a brief active steering intervention is initiated by the system that assists in moving the vehicle back into the original lane (vehicles with the side collision warning (included in the Active Driving Assistant Plus optional equipment OE 5AT)).

The corresponding Blind spot detection indicator flashes in the exterior mirror at the same time.

The steering intervention is initiated within a speed range of between 70 km/h and 210 km/h.

The active steering intervention can be felt on the steering wheel, but can be overridden by the driver at any time. If the driver does override the intervention, the active steering intervention is cancelled.
G12 Driver Assistance Systems
9. Blind Spot Detection

The "steering intervention" for the Blind spot detection can be switched on and off in the iDrive menu in vehicles with the side collision warning by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Intelligent Safety"
- "Steering intervention"

The configuration menu can be accessed quickly by pressing the Intelligent Safety button.

9.3. Limits of the system

The function of the system may not be available or may only be available to a limited extent in the following situations:

- heavy fog, rain or snow
- at sharp bends or on narrow roadways
- if the bumper is dirty, iced up or stickers are placed over it
- if the speed of the approaching vehicle is much higher than the driver's speed
G12 Driver Assistance Systems

10. Side Collision Warning

The side collision warning is part of the active lane keeping assistant with active side collision protection. The active lane keeping assistant with active side collision protection is part of the scope of supply of the Active Driving Assistant Plus optional equipment (OE 5AT). The side collision warning is not available separately.

The side collision warning assists the driver in avoiding a potential side collision.

If an object with which the vehicle could potentially collide, such as a vehicle or a crash barrier, is detected to the side of the driver’s vehicle, the driver is assisted in avoiding the potential collision.

Four radar sensors monitor the area next to the vehicle and function regardless of the lighting conditions and largely irrespective of the weather conditions.

If there is a risk of a collision, the corresponding indicator flashes (depending on which side the risk relates to, left or right) in the exterior mirror with high intensity and the steering wheel starts to vibrate.

An active steering intervention is then initiated, which assists the driver in moving his vehicle back
G12 Driver Assistance Systems

10. Side Collision Warning

to a safe area within his own lane.

The steering intervention is initiated within a speed range of between 70 km/h and 210 km/h.

The active steering intervention can be felt on the steering wheel, but can be manually overridden by the driver at any time.

**Radar sensors**

The rear radar sensors are Blind spot detection (SWW) sensors.

Two additional radar sensors are used for the front side collision warning.
G12 Driver Assistance Systems

10. Side Collision Warning

**Functional prerequisites**

A prerequisite for the activation of the side collision warning with steering intervention is that the lane markings must be detected by the KAFAS stereo camera.

If the lane markings are not detected or if the driver is driving within the speed range of 30 km/h to 70 km/h, only the reduced side collision warning is active. The warning functions in the form of the flashing indicator in the exterior mirror and the vibration of the steering wheel continue to be implemented.

With the reduced side collision warning there is no active lateral guidance of the vehicle. In this case the driver is only warned by a single steering wheel pulse on the opposite side of the wheel to the danger.

The side collision warning can be switched on and off in the iDrive menu by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Intelligent Safety"
- "Side Collision Warning"

The configuration menu can be accessed quickly by pressing the Intelligent Safety button.
G12 Driver Assistance Systems

10. Side Collision Warning

<table>
<thead>

<td>&quot;Side collision warning&quot;</td>
</tr>
<tr>
<td>3</td>
<td>&quot;Side collision warning&quot; (switching the side collision warning with steering intervention on and off)</td>
</tr>
</tbody>
</table>

It is not possible to switch off the steering intervention for the side collision warning separately.

The side collision warning automatically activates itself again after the vehicle moves off if the function was switched on at the time of the last engine shutdown.

10.1. Limits of the system

The function of the system may not be available or may only be available to a limited extent in the following situations:

- heavy fog, rain or snow
- at sharp bends or on narrow roadways
- if the bumper is dirty, iced up or labels are placed over it
- If driving at close proximity to a vehicle driving ahead
- if the speed of the approaching vehicle is much higher than the driver’s speed
The Speed Limit Information optional equipment has been expanded to include the display of most legal signs (i.e. normal speed limit signs, school signs, construction signs) and will be referred to as road sign recognition from now on in this document. Current top speed limitations and no overtaking signs are detected by the road sign recognition system and displayed in the instrument cluster or the Head-Up Display in the form of road sign symbols.

The display of road signs is based on the evaluation of data from the navigation system and the evaluation of image data recorded by the KAFAS stereo camera.

The KAFAS stereo camera detects road signs at the edge of the road and also the variable displays of gantry signs. Road signs containing additional information, e.g. "In wet conditions", are also detected and synchronised with vehicle-internal data, e.g. the rain sensor, and displayed depending on the situation.

The system also takes the applicable time restrictions identified into account, e.g. "between 10.00 pm and 6.00 am". The current time of the on-board clock is used for this. The system takes the information stored in the navigation system into account and displays existing top speed limitations on sections of road without signage.

Road sign recognition (Speed Limit Information) is part of the Active Driving Assistant optional equipment (OE 5AS) in the G12.

⚠️

The system does not relieve the driver of personal responsibility for correctly judging the visibility and traffic situation. The driver is solely responsible for the vehicle and the speed at which it is driven.
11. Road Sign Recognition

11.1. Operation

The road sign recognition can be switched on and off in the iDrive menu by making the following selection via the controller:

- "My Vehicle"
- "System settings"
- "Displays"
- "Instrument Cluster"
- Apply desired settings.

11.2. Limits of the system

Road signs for top speed limitations that do not comply with the legal standard, particularly those without circular frames, are not always detected. The same also applies for traffic signs which are fully or partially covered by labels, dirt or vegetation. Long distances to the road sign, high driving speeds and poor weather conditions, particularly at night, make it more difficult for the system to recognize road signs reliably. To ensure the current top speed limitations are displayed as accurately as possible, the data of the navigation road map should be up-to-date.

The functionality of the road sign recognition may be impaired in the following situations and may lead to incorrect information being displayed:

- heavy fog, rain or snow
- if signs are covered by objects
- If driving at close proximity to a vehicle driving ahead
- Strong light in the camera lens
- if the windscreens in front of the interior mirror is misted over, soiled or covered by stickers, etc.
- as a result of incorrect detection by the camera
- if the top speed limitations stored in the navigation system are incorrect
- in areas not covered by the navigation system
- in the event of deviations from the navigation, e.g. due to modified road layouts
- when overtaking buses or trucks with speed limit stickers
- if road signs do not correspond to the standard
- when calibrating the camera immediately after vehicle delivery.

Supplementary sign recognition

Only additional characters with symbols (icons) can be recognized by the system, such as "in wet weather", "in rain/snow", "truck" or "trailer", etc. Text notes on additional characters can generally not be read or interpreted.
Additional information is requested by the system from the vehicle electrical system before displaying speed limits or no overtaking signs with restrictive validity. For example, for "in wet weather" signs the status of the wiper is evaluated or for "in frost/snow" the temperature value of the outside temperature sensor is evaluated.

Temporal restrictions of the speed limit or no overtaking sign can only be evaluated correctly if the validity duration is stored in the navigation map and the clock is set correctly in the vehicle. Otherwise, the speed limit or the no overtaking sign is displayed as currently valid.

The trailer signal for vehicles in trailer towing is not evaluated for the display of speed limits as the speed limits for vehicles with trailer are specific to the national market and dependent on the trailer type.

Other additional characters are not recognized. The speed limit or the no overtaking sign is then displayed as currently valid without the interpretation of the additional character.

**Road signs on parallel, branching-off or merging roads and on exits**

Parallel roads are not recognized, neither by the KAFAS stereo camera nor with the help of the navigation map. Signs on these roads can be recognized and displayed as speed limits or no overtaking for the current road.

Speed limits and no overtaking signs for forking or emerging roads are generally also assumed and displayed for the current road.

Speed limits for exits off highways with or without an arrow as an additional character are generally evaluated correctly and suppressed in the display if driven past. This is only the case if the data on the navigation map is up-to-date.

In the case of gantry signs on the highway with different, lane-dependent speed limits, the speed limit which is closest to the vehicle's lane is displayed. There is no adaptation of the display after a later lane change.

**Information signs in the road sign surroundings**

Information signs with speed limits or no overtaking stipulations, such as at border crossing points with information on the different legal maximum speeds for single-lane roads and highways, may be incorrectly recognized as currently valid and displayed. The same applies to information signs with different color configurations, for example for minimum or recommended speeds.

**Stickers on vehicles**

Stickers with a speed limit on vehicles ahead or overtaken, such as trucks, buses, trailers or construction machinery, etc., may be incorrectly recognized as a currently valid speed limit and displayed.

**Town/city limits**

If the sign for the entrance to a village/town is not clearly recognized and the data from the navigation map is not up-to-date, the speed limit at the entrances to and exits from villages/towns may be displayed incorrectly.

**Legal changes**

If legally prescribed maximum speeds change, then these are only available after a software update. Up until the update the original, current but no longer valid speed limits are displayed.
11. Road Sign Recognition

General no overtaking signs

No overtaking signs are only displayed if these are also signs posted. General no overtaking stipulations, for example that apply at level crossings or are marked by a continuous white line on the roadway, are not displayed unless an additional sign is present.

⚠️
The system does not replace the personal assessment of the traffic situation. Due to system restrictions and functional limitations, it may transpire that warnings and orders are not issued, are issued too late or are unwarranted. The road sign recognition supports the driver and does not replace the human eye.
G12 Driver Assistance Systems
12. Proactive Active Driving Assistant

The proactive Active Driving Assistant points out to the driver the ideal time at which to release the accelerator in order to reduce consumption, thus enabling the driver to save fuel.

Data from the navigation system is evaluated as the basis for the calculation. Using this data, sections of road ahead that require a reduction in speed can be detected in good time.

Relevant sections of road are:

- Intersections
- Bends
- Crossroads
- Roundabouts
- Entrances to towns
- Top speed limitations
- Highway exits

The proactive Active Driving Assistant function is available in the G12 in conjunction with the Navigation System Professional optional equipment (OE 609).

To ensure the coasting function is used to its full potential, the proactive Active Driving Assistant takes into account whether coasting is currently possible and adapts the time that the information is issued accordingly. The proactive Active Driving Assistant actively cancels coasting if it is possible to reach a section of road ahead in coasting overrun mode.

The proactive Active Driving Assistant helps drivers who are not familiar with the route or area to drive more efficiently.

Display

An indicator in the instrument cluster or Head-Up Display (only with optional equipment OE 610) alerts the driver that he is on a section of road relevant for the proactive Active Driving Assistant and gives him the option to react accordingly.

The driver can activate or deactivate the indicator in the Head-Up Display separately.
The alert is issued even if the section of road ahead cannot yet be seen by the driver. This information is displayed in the instrument cluster or Head-Up Display (optional equipment OE 610) until the road section is reached. If the vehicle is decelerated considerably before reaching the road section, the indicator goes out before the section is reached.

The maximum length of road section that can be displayed is restricted to approximately 1500 m.

An additional symbol displays the detected road section in the instrument cluster.

<table>
<thead>
<tr>
<th>Display in the instrument cluster (additional symbol)</th>
<th>Display in central information display</th>
<th>Explanation</th>
</tr>
</thead>

</tr>
<tr>
<td><img src="image7.png" alt="Speed Limit Symbol" /></td>
<td><img src="image8.png" alt="Speed Limit Symbol" /></td>
<td>Speed limit on the route</td>
</tr>
</tbody>
</table>

In the driving style analysis display on the central information display information is shown when a corresponding road section lies ahead.
In the driving style analysis view the driver also has the option of displaying information on his driving style.

The ECO PRO driving style analysis display consists of a symbolized road route and a table of values. The road symbolizes the efficiency of the driving style. The more efficient the driving style the smoother the route. The table of values contains stars. The more efficient the driving style, the more stars there are in the table and the quicker the bonus range increases.

ECO PRO notes are displayed during the journey as support for an efficient driving style.
12. Proactive Active Driving Assistant

12.1. Operation

To use the proactive Active Driving Assistant, ECO PRO mode or ECO PRO+ mode must be activated via the driving experience switch.

The proactive Active Driving Assistant can be switched on and off in the ECO PRO configuration menu.

To call up the display of the driving style analysis, make the following selection via the controller:

- "My Vehicle"
- "Technology in action"
- "Driving style analysis"
The proactive Active Driving Assistant can be used when the route guidance is either active or inactive. When the route guidance is not active, the most likely route is used for evaluation. However, the calculation can be performed more accurately, and therefore more efficiently, when the route guidance is active.

⚠️
The reliability of the system depends on the up-to-dateness and quality of the navigation data.

### 12.2. Limits of the system

The proactive Active Driving Assistant is not available in the following situations:

- Speed below 50 kph
- Temporary and variable top speed limitation, such as on building sites
- Quality of navigation data insufficient
- Cruise control active
- Trailer towing
G12 Driver Assistance Systems

13. Alertness Assistant

The attentiveness assistant helps to avoid accidents caused by tiredness on long, monotonous journeys. It is part of the Active Protection equipment (OE 5AL) included in the basic equipment.

A change in the driver’s driving behavior is perceived by the attentiveness assistant. In the event of increasing inattentiveness or if the driver is tired, the alertness assistant shows a display recommending that the driver take a break as a Check Control message in the central information display (CID).

The alertness assistant is automatically active after each engine start from a speed of roughly 70 km/h. If the system is active, a driving behavior profile is created at the beginning of a journey. The following criteria are taken into consideration:

- Personal driving style, for example the steering behavior
- Driving conditions, for example the time or journey duration
- Breaks during a long journey
- Journey duration.

13.1. Operation

If the changed driving behavior differs markedly from the taught-in driving behavior of the alertness profile, the alertness assistant shows a break recommendation in the central information display (CID).

While the display is shown on the central information display (CID) the following settings can be selected using the controller:

- "Do not ask again"
- "Places to stop"
- "Remind me later" (in this case the break recommendation appears again after a journey duration of 20 minutes).

The break recommendation is only displayed once during an uninterrupted journey (except when "Remind later" is selected).

After a break a new break recommendation is not shown during the next 45 minutes of the journey. The system is reset if a break is longer than 50 minutes or if the break lasts longer than the last driving time. The driving behavior is re-taught.

The attentiveness assistant can be switched on and off in the iDrive menu. The driver can also set the level of sensitivity in this menu by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Attentiveness Assistant"
- Select desired settings.
G12 Driver Assistance Systems

</tr>
<tr>
<td>&quot;Off&quot;</td>
<td>A break recommendation is not issued.</td>
</tr>
</tbody>
</table>
13.2. Limits of the system

The functionality may be impaired in the following situations and no warning or an incorrect warning may be issued:

- If the clock is set incorrectly
- If the speed is predominantly below approximately 70 km/h
- If the driver adopts a sporty driving style, for example rapid acceleration or fast cornering
- In active driving situations, for example frequent lane changes
- Poor road condition
- Strong crosswind.

⚠️
The system does not relieve the driver of personal responsibility for correctly judging his physical condition. Increasing inattentiveness or fatigue may not be detected at all or in time.
G12 Driver Assistance Systems

14. Night Vision

In the G12 the Night Vision system is available in the form of BMW Night Vision with person and animal recognition optional equipment (OE 6UK).

Night Vision detects people and animals in optimum conditions at night up to a distance of approximately 100 m away and therefore assists the driver especially on dark and difficult stretches of road, such as when driving on single-lane roads with adjacent woods.

In potentially dangerous situations, the system warns the driver of people and animals on the road.

The Night Vision camera integrated in the BMW radiator grille records the area in front of the vehicle and sends the data to the Night Vision electronics (NVE).

Heating is switched on to avoid ice forming on the camera at temperatures below 5° C.

The image data is analyzed by the Night Vision electronics control unit and the corresponding image information is sent to the head unit via the Color Video Blanking Signal.
Hot objects with outlines that resemble people or animals are detected by the system and can be displayed on the central information display if necessary.

<table>
<thead>
<tr>
<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Night Vision camera detection range</td>
</tr>

<td>2</td>
<td>Night Vision camera image showing detected person (display on the central information display)</td>
</tr>
<tr>
<td>3</td>
<td>Night Vision camera image showing detected animals (display on the central information display)</td>
</tr>
</tbody>
</table>

Object detection range

- Person recognition: up to about 100 m
- Recognition of large animals: up to about 150 m
- Recognition of medium-sized animals: up to about 70 m

Night Vision detects people and determines their position and distance from the vehicle. Taking into account the driving speed and steering angle, the system calculates whether there is a potential risk and displays a warning sign (early warning) in the instrument cluster and in the Head-Up Display, if present.

In critical situations a warning signal also sounds (acute warning).

The warning threshold values are also dependent on whether the person or the animal is moving or standing still. This is highlighted in the following graphic.

**Early warning**

The early warning is effected if a person or animal is detected inside the warning range. The early warning shows, depending on the location of the person or animal, a person or animal in yellow which is located inside the actual lane or is moving into the lane. Animals from a certain height can be detected, for example deer.
G12 Night Vision warning ranges (early warning)

<table>
<thead>
<tr>
<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>

</tr>
<tr>
<td>3</td>
<td>Warning range, early warning (person on the roadway)</td>
</tr>
<tr>
<td>4</td>
<td>Warning range, early warning (person crosses the roadway)</td>
</tr>
</tbody>
</table>

**Acute warning**

The acute warning is only effected in the case of immediate danger of a collision. The time of the acute warning is measured so that a collision can only be avoided by immediate emergency braking or by swerving. With the acute warning the brakes of the vehicle are prepared for emergency braking.

The acute warning in the instrument cluster and in the Head-Up Display shows a red flashing person or animal symbol on the roadway. In addition, an acoustic warning signal is sounded.

</tr>
</tbody>
</table>

Display in the central information display (CID)

The pedestrian or animal warning is effected irrespective of the representation of the Night Vision camera image in the central information display CID.

The warning is no longer shown on the central information display, but instead only appears in the instrument cluster and on the Head-Up Display. If the Night Vision camera image is active, identified pedestrians and animals are shown in yellow.

G12 Driver Assistance Systems

14. Night Vision

14.2. Operation

Night Vision is automatically switched on every time the vehicle sets off when it is dark. The warning functions are therefore issued irrespective of the view on the central information display. The driver can switch the Night Vision camera display on the central information display on and off by pressing the Night Vision button in the light operating unit.

It is also possible to set the brightness and contrast of the Night Vision display via the iDrive.

<table>
<thead>
<tr>
<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Night Vision button</td>
</tr>
</tbody>
</table>
14.3. Limits of the system

The functionality may be impaired in the following situations and no warning or an incorrect warning may be issued:

- On steep summits or dips and tight bends
- If the camera is dirty or the protective screen is damaged
- In heavy fog, rain or snow
- If the outside temperatures are very high

The person and animal recognition may also be impaired or may not issue the usual warnings. This can occur in the following cases:

- If the person or animal is fully or partially hidden, particularly the head
- If the person is not in an upright position, e.g. if they are lying down
- If a bike has non-conventional wheels, e.g. recumbent bicycle
- If the system has been affected mechanically, e.g. after an accident

In certain cases small animals may be entirely visible on the central information display, but may not be identified by the object detection. As a consequence, a warning is also not issued.

⚠️

The system does not relieve the driver of personal responsibility for correctly judging the visibility and traffic situation. The driver is solely responsible for the vehicle and the speed at which it is driven.
The optional equipment Surround View (SA 5DL) is part of ZDB Driver Assistance Plus and provides support when parking, maneuvering, as well as at unclear exits and crossroads. In the G12, the Surround View optional equipment (OE 5DL) is only available in conjunction with the rear view camera optional equipment (OE 3AG).

Panorama View is part of the Surround View optional equipment (OE 5DL).

The rear view camera is available as standard equipment (OE 3AG).

15.1. Surround view

The Surround View optional equipment (OE 5DL) shows the vehicle surroundings and displays them in TOP View and 3D View on the central information display.

The system comprises the front camera, the two cameras integrated in the exterior mirrors, the rear view camera (RFK) and the top rear side view camera (TRSVVC) control unit. The cameras record the area from various, selectable angles and send this information to the TRSVVC control unit via Ethernet. The images from the four cameras are combined into a panorama view around the vehicle from different angles using 3D computer graphics. The video signals are transmitted from the TRSVVC control unit via an Ethernet line to the head unit. From there the video signal is transmitted to the central information display via an Automotive Pixel Link line. The driver can choose from preset views or can freely select the view (for example towbar zoom and car wash entrances).

In addition, assistance functions such as guidance lines can be shown on the central information display.

</tr>
</tbody>
</table>
G12 Driver Assistance Systems

15. Cameras

The following camera angles can be displayed:

- Automatic camera angle
- Side view
- Front camera
- Panorama View
- Reversing camera
- Moving camera angle

15.1.1. Automatic camera angle

The system automatically shows the most appropriate camera angle depending on the driving situation, thus providing the driver with optimum assistance when parking and maneuvering. The automatic camera angle shows a steering-dependent view and takes into account the respective direction of travel and the distance information from the Park Distance Control (PDC).

As soon as obstacles are detected, the view changes to a fixed display of the area in front of or behind the vehicle, or changes to the corresponding side view if required.

15.1.2. Side view

This view helps the driver to position the vehicle next to the curb or other obstacles at the side of the vehicle by displaying the side surroundings. The side view is from the rear to the front and automatically focuses on potential obstacles if there is a collision risk.

Both the left and right sides of the vehicle are recorded.

15.1.3. Front camera

The front camera supports the driver when parking and maneuvering. The area in front of the vehicle is recorded by the front camera and shown on the central information display. The front camera view cannot be selected separately. The driver must select the "Auto" camera angle to view it or if desired, switch on the "Panorama View" function (see next section).
G12 Driver Assistance Systems

15. Cameras

Areas around the vehicle that are not visible due to the camera angle of view are shown with grey crosshatching.

15.1.4. Panorama View

Panorama View enables the driver to see the cross traffic at blind exits and intersections before proceeding and provides the driver with optimum assistance in this situation. Road users that are hidden by obstacles to the side of the vehicle are sometimes only seen by the driver very late or not at all. To improve the view, the front and rear view cameras record the lateral roadway area. Depending on which drive position is engaged, the front or rear view camera can be activated.
G12 Driver Assistance Systems
15. Cameras

Yellow lines in the screen display mark the front and rear ends of the vehicle. The camera image is badly distorted in some areas and is therefore not suitable for estimating distances.

The function can be activated using the Panorama View button. Press the button again to deactivate the function. The Panorama View function is automatically deactivated at speeds above approximately 15 km/h. Panorama View is also deactivated after a drive position change (from "D" to "R" or the opposite).

Panorama View (GPS-based)

The GPS-supported, automatic activation of the Panorama View function has been implemented in the G12.

Positions, at which the Panorama View should switch itself on automatically, can be saved as activation points, provided that a GPS signal is received. A maximum of ten activation points can be saved for the front camera.

To save the activation points, the driver must proceed as follows:

Stop after reaching the place where the Panorama View should switch itself on automatically. Press the Panorama View button and then tilt the controller to the left. Then select "Add activation point" (the current position is displayed) and confirm by selecting "Add activation point".
If possible, the activation points are saved with the town/city and street or with the GPS coordinates. The direction of travel is also saved in conjunction with the activation point.

The driver can display the saved activation points on the central information display.
G12 Driver Assistance Systems

15. Cameras

The use of activation points can be switched on and off via iDrive.

G12 displaying activation points

**Index** | **Explanation**
---|---
1 | "Show activation points"

G12 Panorama View activation menu on the CID
15. Cameras

15.1.5. Reversing camera

The rear view camera supports the driver when parking and maneuvering. The area behind the vehicle is recorded by the rear view camera and shown on the central information display.

15.1.6. Moving camera angle

When the moving camera angle is selected, a circular trajectory is shown around the vehicle on the central information display. Predetermined angles can be selected on the circular trajectory by turning the controller or using the touch function.

In vehicles with the gesture control optional equipment (OE 6U8), the moving camera angle can also be controlled in this way.

The current angle is identified by a camera symbol. Depending on the view, the surroundings of the vehicle or a partial area of the surroundings are shown on the central information display.
G12 Driver Assistance Systems

15. Cameras

To leave this view, tilt the controller to the side, press it or touch the highlighted camera symbol via the touch screen.

If gesture control is being used, the gesture symbol is shown on the right half of the central information display screen.
15.2. Overview of exterior camera operating menu

Once the camera systems have been activated successfully the driver has the option of selecting the appropriate view or camera via iDrive.

<table>

G12 operating menu for exterior cameras and Parking Maneuver Assistant
G12 Driver Assistance Systems

15. Cameras

15.3. Assistant function

If required, the driver can receive additional assistance from the "Car wash" functions.

15.3.1. Car wash view

The car wash view assists the driver when entering a car wash. When the car wash view is selected, immediately before entering the car wash, a bird's eye view is displayed on the central information display. To enable the driver to align the vehicle more easily, at the same time the vehicle's tire tracks are shown on the display.

The car wash view can be activated via iDrive in the toolbar under the "Car wash" menu item.

<table>
<thead>
<tr>
<th>Index</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>&quot;Car wash&quot;</td>
</tr>
</tbody>
</table>

15.3.2. Side protection

The side protection warns against obstacles at the side of the vehicle and thus supports the driver when parking and maneuvering.

To protect the sides of the vehicle from collisions with obstacles, additional obstacle markings are shown to the side of the vehicle on the central information display if necessary, these obstacles are tracked by the nearest camera.
More information on the side protection function can be found in section 18.

15.3.3. Door opening angle

When the vehicle is stopped and the selector lever position "P" is engaged, the maximum opening angle of the doors is displayed on the central information display.

If there is an obstacle near the door and it is detected by the side protection, this is marked on the central information display. The obstacle marking display only points out objects in the area of the door. It is not possible for a view from the camera systems to be displayed, as the door area is simulated. Therefore, the driver is only informed that there is an object at the side of the vehicle; it is not certain that the door will definitely collide with the identified object. The driver must judge this for himself.
The "Parking assistance lines" and "Obstacle marking" features already used in other BMW models can also be activated and deactivated via iDrive in the toolbar under the relevant menu items.

⚠️
The camera systems do not relieve the driver of personal responsibility for correctly judging the traffic situation. There is still a risk of an accident. The driver's driving style should be adapted to the traffic conditions. The driver should check the traffic conditions and the vehicle's surroundings by looking around and react accordingly if required.

15.4. System components

Front camera

The front camera is installed in the center between the two front ornamental grilles on the G12.
G12 Driver Assistance Systems

15. Cameras

Top view camera

The two top view cameras are installed in the exterior mirrors on the G12.

15.4.1. Reversing camera

The rear view camera supports the driver when parking and maneuvering. The area behind the vehicle is shown on the central information display. Guidance lines integrated in the image provide the driver with additional assistance with distances, the turning circle and obstacle markings function, if required.

The driving lane lines are dependent on the steering angle and are continually adjusted when steering wheel movements are made.

The turning circle lines can only be shown in the rear view camera image in conjunction with the driving lane lines. The turning circle lines show the shape of the smallest possible turning circle on an even roadway. From a certain steering-wheel angle, only one turning circle line is shown.

The rear view camera is located in the tailgate handle strip.
G12 Driver Assistance Systems

15. Cameras

The control unit is integrated in the rear view camera and is the bus user at K-CAN3. The video signals are transmitted directly to the Head Unit High 2 (HU-H2) via a CVBS line. An Ethernet connection for the rear view camera (on non 5DL cars) is being planned for a later version.

In vehicles with the Surround View optional equipment (OE 5DL) a rear view camera without an integrated control unit is installed. The reversing camera is connected to the TRSVC control unit via Ethernet in vehicles with Surround View (SA 5DL).

15.4.2. TRSVC control unit

The exterior cameras record the area around the vehicle from various angles and send this information to the TRSVC control unit via Ethernet. The video signals are transmitted from the TRSVC control unit to the head unit via an Ethernet line. The head unit transmits the signals to the central information display via an Automotive Pixel Link line.

The installation location of the TRSVC control unit is in the footwell on the driver's side.
G12 Driver Assistance Systems

15. Cameras

15.5. System wiring diagram

The system wiring diagram on the next page shows an overview of the system components used when parking and maneuvering the vehicle. Depending on the vehicle equipment, partial scopes may also be installed.

G12 Driver Assistance Systems

16. Park Distance Control

Park Distance Control (PDC) assists the driver when maneuvering in and out of a parking space. The current distance from an obstruction is indicated by acoustic signals and on a visual display.

The front and rear Park Distance Control (OE 508) is included in the G12 standard equipment.

The distance from an obstruction is measured by four ultrasonic sensors in the rear bumper panel and four additional ultrasonic sensors in the front bumper panel.

16.1. System components

Vehicles that do not have the Parking Maneuver Assistant but do have the Park Distance Control have a separate control unit, which is recognized as the PMA control unit by diagnosis and is also referred to by this name in the bus diagram. In other words, there is no longer a difference in the naming of the PDC and PMA control unit (there are however differences in the hardware design between the control units and the software is adapted to the equipment specification).

16.2. Auto PDC

Automatic activation of the Park Distance Control not only with drive position "R" engaged, but also with "D" engaged, has been implemented in the G12.

Auto PDC is also activated automatically if the vehicle is approaching an object at a speed below approximately 5 km/h.

Use case:

The driver is driving along a road at approximately 50 km/h and after some time approaches an entrance gate on the right-hand side of the road. The entrance gate is 2.80 m wide and there is a wall on each side of it. The vehicle turns right to drive into the entrance gate. Let us assume that in this example space is very restricted and given the difficult curve radius the vehicle is approaching the left-hand wall of the entrance gate at a distance of less than approximately 0.6 m. In this case, the Park Distance Control would be activated automatically, if on approaching the wall the speed of the vehicle does not exceed approximately 4 km/h.

The Park Distance Control is activated automatically, if:
G12 Driver Assistance Systems
16. Park Distance Control

- there is an object closer than 0.6 m from the front of the vehicle when driving forwards
- there is an object closer than 1.5 m from the rear of the vehicle when reversing
- the speed driven does not exceed approximately 4 km/h

The PDC view is automatically displayed on the central information display. The activation distance of the Park Distance Control depends on the respective situation and therefore may vary.

A sound is only output if the detected object (in front of or behind the vehicle) is directly in the lane (risk of collision). If the detected object is not directly in the lane, there is only visual acknowledgement on the central information display.

<table>
<thead>
<tr>

</tr>
<tr>
<td>3</td>
<td>Detection of obstacle by the ultrasonic sensors</td>
</tr>
</tbody>
</table>

If an object has been detected by Auto PDC, the system must be reactivated so that it cannot be accidentally switched on, for example in a car wash. Reactivation is effected by:

- driving speed > 5 km/h
- drive position change

If a drive position change is made into neutral, the Park Distance Control is not activated automatically, again to avoid it being switched on, for example in a car wash.

The automatic switch-on function when obstacles are detected can be switched on and off via iDrive.
16.3. Active Park Distance Control

In G12 vehicles with the Parking Maneuver Assistant optional equipment (OE 5DP), the Park Distance Control function has been extended to include the active Park Distance Control function. This automatically brakes the vehicle to a halt when it is travelling at walking speed ( < approximately 6 km/h) if an object is detected behind the vehicle.

If the accelerator pedal is pressed and an obstacle is detected, the brakes are preconditioned and gentle initial braking is initiated as a warning for the driver. If the accelerator pedal is not pressed and the vehicle is very close to the obstacle, the function brakes the vehicle with the maximum possible brake force until it comes to a standstill. This can potentially avoid a collision or reduce the damage.

The automatic brake intervention can be overridden at any time by pressing the accelerator pedal. Consequently, after the vehicle is automatically braked to a standstill, it is possible to continue to approach the obstruction by gently pressing the accelerator pedal.

The active Park Distance Control function can be switched on and off via iDrive.

If the Dynamic Stability Control (DSC) is switched off, then the active Park Distance Control is also deactivated. If the active Park Distance Control is switched on when the Dynamic Stability Control is switched off, the DSC is automatically switched on at the same time.

⚠️
The system does not relieve the driver of personal responsibility for correctly judging the traffic situation. The driver should check the traffic conditions and the vehicle's surroundings by looking around and react accordingly if required.

16.4. Side protection

Vehicles with the Parking Maneuver Assistant optional equipment (OE 5DP) have side protection. Obstacles that are detected by the four side ultrasonic sensors integrated in the bumpers can be displayed by the Park Distance Control system.

<table>
<thead>
<tr>
<th>Display in the central information display (CID)</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colored markings</td>
<td>Warning of detected obstacles</td>
</tr>
<tr>
<td>Grey markings</td>
<td>The area next to the vehicle has not yet been recorded</td>
</tr>
<tr>
<td>No markings</td>
<td>No obstacles have been detected</td>
</tr>
</tbody>
</table>

The system only shows stationary obstacles that were earlier detected by the ultrasonic sensors when driving past.

It is not able to detect whether an obstacle has since moved. For this reason, the markings on the display are shown in grey after the vehicle has been stationary for roughly 13 seconds.

More information on the side protection function can be found in section 18.6.
16.5. Operation

The Park Distance Control system is enabled in the following situations:

- if drive positions R or D are engaged when driving readiness is switched on
- if the parking assistance button in the switch block next to the controller is pressed when driving readiness is switched on
- if Auto PDC is activated and all marginal conditions for automatic activation are met (see section 16.2 "Auto PDC").

16.5.1. Auto PDC

Automatic switch-on of this function when obstacles are identified can be switched on and off in the "Settings" menu using the controller. To do this proceed as follows:

- "My Vehicle"
- "Vehicle settings"
- "Parking"
- "Automatic PDC activation"
- Apply desired setting.
The setting is stored for the ID transmitter currently being used.

16.5.2. Active Park Distance Control

The active Park Distance Control function can be switched on and off in the "Settings" menu using the controller. To do this proceed as follows:

- "My Vehicle"
- "Vehicle settings"
- "Parking"
- "Active PDC emergency inter."
- Apply desired setting.

The setting is stored for the ID transmitter currently being used.
The driver is notified about the results of the distance measurements and the distance warnings acoustically via the audio speakers and optically via the central information display (CID). As the vehicle approaches an object, the corresponding position is indicated by an intermittent tone from the audio speaker. If, for example, an object is detected behind the vehicle to the left, the rear left speaker emits an acoustic signal. A continuous alarm sounds when the object is about 25 cm or less away. The volume of the acoustic signal of the Park Distance Control system can be adjusted in relation to the audio playback of the entertainment system.
16.6. Deactivation criteria

Similar to other BMW models, the deactivation is distance-/speed-based. The switch-off is effected after a journey of about 50 m or at a speed over 36 km/h.

If a fault develops, a Check Control message ("PDC has malfunctioned. Have system checked.") is displayed in the central information display (CID). In addition, the detection range of the sensors is shown shaded in the central information display (CID).
16.7. Limits of the system

Due to the physical limits during the ultrasonic measurement, obstructions may not be detected by the Park Distance Control system. Several examples of this are shown below:

- if the objects are thin or wedge-shaped
- when the objects are low
- when objects that, due to their shape, have corners and sharp edges
- with snow
- if the objects have a porous surface.

A warning may also be displayed although there is no obstruction in the detection range. This may be the case in the following situations:

- when it is raining heavily
- if the sensors are heavily soiled or iced over
- if the sensors are covered with snow
- if the street surface is rough
- if there are bumps, e.g. speed bumps
- in large right-angled buildings with smooth walls, e.g. underground car parks
- due to heavy exhaust gas fumes
- due to other ultrasound sources.

To ensure the ultrasonic sensors remain fully operational, they must be kept clean and free of ice. When cleaning the sensors using a high pressure cleaner, avoid direct and sustained contact with a high-pressure water jet. Furthermore, when using high pressure cleaners, a distance of at least 30 cm from the sensors must be maintained.

⚠️

The Park Distance Control cannot replace the driver's personal judgement of the traffic situation. Also check the traffic situation around the vehicle by looking around, otherwise there may be a risk of an accident as a result of road users or objects which lie outside the detection range of the Park Distance Control. Loud sound sources outside and inside the vehicle could drown out the PDC signal.
17. Cross-Traffic Warning

The cross-traffic warning is used for the first time in the G12. This warning assists the driver when maneuvering out of a parking space and in other everyday situations where it is difficult to see the traffic, such as at blind entrances and exits.

Depending on the vehicle equipment, the cross-traffic warning is available for the front and rear.

The system can detect objects that are approaching the vehicle from the side, either from the front or rear (depending on the vehicle equipment). The driver is made aware or, if necessary, warned of cross traffic by the cross-traffic warning when maneuvering out of a parking space or entering the cross traffic.

17.1. Functional principle

If a moving object is detected, which based on the current speed would be in the area in front of or behind the vehicle in approximately the next three seconds, a visual and acoustic warning is issued.

When a rear cross-traffic warning is issued, the LED in the mirror glass is also switched on. The Blind spot detection signal unit is used as an indicator. The indicator is switched on in either the left or right mirror depending on the direction from which the object is approaching the vehicle.

The cross-traffic warning works up to a speed of approximately 7 km/h. Another prerequisite of the function is that the side radar sensors are able to detect the road or approaching object. The radar sensors can detect objects up to approximately 30 to 40 m away from the vehicle.

G12 cross-traffic warning example: maneuvering out of a parking space

Depending on the vehicle equipment, different versions of the cross-traffic warning and displays on the central information display are available.
G12 Driver Assistance Systems

17. Cross-Traffic Warning

17.2. Rear cross-traffic warning

The rear cross-traffic warning assists the driver when reversing out of a parking space and warns of potential collisions with cross traffic in traffic situations where it is difficult to see obstructions.

The rear cross-traffic warning function is included in the Active Driving Assistant (OE 5AS) optional equipment.

The warning is displayed in the Park Distance Control image on the central information display.

In conjunction with the rear view camera optional equipment (OE 3AG), the rear cross-traffic warning will be extended to include an additional display on the central information display in a later version. The warning will be shown in the form of a red bar in the camera's video screen.

The rear cross-traffic warning is enabled if the driver engages the "R" drive position or the Park Distance Control is active.

In vehicles with the Surround View optional equipment (OE 5DL), the rear cross-traffic warning is also enabled if Panorama View has been activated.

The rear cross-traffic warning is available at speeds from 0 to approximately 7 km/h.

17.3. Front cross-traffic warning

The front cross-traffic warning assists the driver when entering the cross traffic from exits and blind intersections.

The front cross-traffic warning is included in the Active Driving Assistant Plus (OE 5AT) optional equipment. If the cross-traffic warning for the front of the vehicle is installed, the rear version is activated automatically.

The warning is displayed in the Park Distance Control image on the central information display.

The front cross-traffic warning is enabled if the Park Distance Control is active and the speed of the vehicle does not exceed approximately 7 km/h.

In vehicles with the Surround View optional equipment (OE 5DL), the front cross-traffic warning is also enabled if Panorama View has been activated.

Like the rear cross-traffic warning, the front cross-traffic warning function is available at speeds from 0 to approximately 7 km/h.
17. Cross-Traffic Warning

17.4. Displays

The respective peripheral region in the PDC view flashes red if vehicles are detected by the sensors.

In vehicles with the Surround View optional equipment (OE 5DL), the warning is shown on the central information display in the PDC view image and in the front camera and rear view camera video images in the form of a red bar.

If Panorama View is activated, the cross-traffic warning is shown in the form of a red bar on the central information display.

The cross-traffic warning is available to the driver for both the front and rear views.
G12 Driver Assistance Systems

17. Cross-Traffic Warning

17.5. Operation

The cross-traffic warning can be switched on and off in the iDrive menu by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Parking"
- "Cross-traffic alert"
If the cross-traffic warning has been activated in the iDrive menu, the function is switched on automatically as soon as the Park Distance Control or Panorama View is active.

The cross-traffic warning is deactivated automatically in the following situations:

- if the driver’s vehicle is travelling at a speed higher than walking speed (threshold value approximately 7 km/h)
- if the steering and lane control assistant is active
- if the driver is currently parking using the Parking Maneuver Assistant

### 17.6. Limits of the system

The function may be restricted in the following situations:

- if there are other objects in the field of view of the sensors that are concealing the cross traffic
- In heavy fog, rain or snow
- if the bumper is dirty or iced up
- if stickers have been attached near the radar sensors on the bumper
- if the speed of the approaching vehicle is very high
- if crossing objects are moving very slowly
- on sharp bends

If a trailer socket is being used, for example to operate a trailer or bicycle carrier, the cross-traffic warning is not available for the area behind the vehicle.
18. Parking Maneuver Assistant

The Parking Maneuver Assistant PMA supports the driver in many ways. The assistant measures the size of a gap between cars and decides based on the result whether the gap is large enough on the one hand and relieves the driver of the task of maneuvering into the space on the other. The Parking Maneuver Assistant (OE 5DP) is optional equipment in the G12 and can only be ordered in conjunction with the rear view camera optional equipment (OE 3AG) and its offered as part of the ZDB - Driver Assistance Plus (5AS) package.

18.1. System components

Below is an overview of important sensors and operating elements:

- The parking assistance button is the central control panel for the Parking Maneuver Assistant function (position 8).
- Two additional ultrasonic sensors in the front bumper measure parking spaces while driving (position 1).
- The distance from an obstruction is measured by four ultrasonic sensors in the rear bumper panel and four additional ultrasonic sensors in the front bumper panel (positions 11 and 19).
- Two additional ultrasonic sensors are installed in the rear bumper to precisely detect the size of a transverse parking space during the parking maneuver. The additional ultrasonic sensors measure the distance to detected objects.

18.3. Control unit

In vehicles with the Parking Maneuver Assistant optional equipment (OE 5DP), the Park Distance Control and Parking Maneuver Assistant functions are provided by the PMA control unit.

18.4. Functional principle

The Parking Maneuver Assistant function facilitates maneuvering into parking spaces that are parallel (parallel parking) and perpendicular (bay parking) to the roadway. The system measures potential parking spaces when driving past at a speed below approximately 35 km/h without the system having been activated.

The parking spaces are measured by two additional ultrasonic sensors, which are integrated into the front wheel arch. These two sensors are connected to the Parking Maneuver Assistant (PMA) control unit, which also incorporates the Park Distance Control function. The function of the two ultrasonic sensors is similar to that of the Park Distance Control PDC. Ultrasonic pulses are sent and echo impulses are received.

Two additional ultrasonic sensors are installed in the rear bumper of the G12 to precisely detect the size of a transverse parking space during the parking maneuver. The additional ultrasonic sensors measure the distance to detected objects.

If a parking space of a sufficient length and width is found and the system is activated, the driver is shown the space on the central information display.

The Parking Maneuver Assistant function then takes over the vehicle handling entirely, including steering, braking and gear selection.

Spaces that do not have a vehicle at either side are also recognized as suitable parking spaces. This makes it possible to park behind only one object.

The driver is still responsible for monitoring the vehicle environment and can intervene in the automatic parking maneuver at any time if required due to the vehicle environment. When searching for a parking space and when parking, all relevant information is presented to the driver in an integrated display; from the parking space itself to the status of the parking assistant and corresponding handling instructions through to distances from other objects.
G12 Driver Assistance Systems
18. Parking Maneuver Assistant

Personal responsibility:

• Directly monitor gaps and the parking procedure and intervene if necessary, as otherwise there is a risk of accidents.
• If a parking space that has already been measured changes, the system does not take this into account.
• The system does not take loads that project above the vehicle into account during parking.
• The Parking Maneuver Assistant PMA may steer the vehicle over or up onto curbs. You should therefore use the facility for active intervention at any time with caution as you may otherwise damage wheels and tires or the vehicle itself.

⚠️ The Parking Maneuver Assistant PMA does not relieve the driver of personal responsibility during parking. Therefore, be attentive in order to be able to actively intervene at any time. Otherwise, there is a risk of an accident.

18.5. Functional prerequisites

To use the Parking Maneuver Assistant function, the following basic prerequisites must be met:

• the doors must be closed
• the tailgate must be closed
• the driver’s seat belt must be fastened
• the parking brake must be released

18.5.1. Measuring parking spaces

Parking spaces are measured while driving. The following parameters apply:

• Driving forwards straight-ahead up to about 35 km/h
• Maximum distance to the row of parked vehicles: 1.5 m.

Detecting the curb

If a curb is detected within the range of the ultrasonic sensor while the system is searching for a parking space, the parking space is for the most a space that is parallel to the road.

In the case of parking spaces that are perpendicular to the roadway, the curb is usually outside the detection range of the ultrasonic sensors (range about 4.2 m).
18.5.2. Suitable parking spaces parallel to the roadway (parallel parking)
Size of parking space | vehicle length plus about 0.8 m
---|---
Length of objects | at least 0.5 m
Minimum number of detected objects | 1
Minimum depth of parking space | about 1.5 m

The minimum length of an object detected by the vehicle must be approximately 0.5 m. With an object length of 0.5 m, a curb must still be detected by the PMA sensors for the purpose of parking in a parallel (curbside) parking space so as to ensure that the parking space is a parallel one.

Index | Explanation
---|---
1 | Maximum distance to the row of parked vehicles or objects: 1.5 m
2 | Opening angle of the ultrasonic sensor horizontal: ± 40°, range about 4.2 m
3 | Length of the parking space: vehicle length plus about 0.8 m
4 | Object or vehicle length at least 0.5 m
18.5.3. Suitable parking spaces perpendicular to the roadway (bay parking)

The depth of perpendicular (cross) parking spaces must be gauged by the driver himself. Due to technical limits the system can only approximately determine the depth of perpendicular (cross) parking spaces.
## G12 Driver Assistance Systems

</tbody>
</table>
Different bay parking spaces

1. Standard parking space between two passenger cars

2. Parking space with post (underground car park)

3. Parking space with obstacles (public car park)
18.5.4. Detection of a universal parking space

Due to the technical system limits, the vehicle does not always detect the correct parking space. Situations may occur where parking spaces are wrongly detected, or parking spaces that are unsuitable or not actually classed as parking spaces are detected.

The below graphic shows a situation where this may be the case.

The detected parking space is big enough to park the vehicle in both perpendicularly and parallel to the roadway. Because of the absence of a curb, the vehicle cannot correctly determine the parking space. The vehicle proposes a universal parking space. In this case, the driver must decide how he wants to maneuver into the parking space.

The following display appears on the central information display when the vehicle has detected a universal parking space.
18. Parking Maneuver Assistant

**18.6. Side protection**

The side protection warns against obstacles at the side of the vehicle and thus supports the driver when parking and maneuvering.

Four side ultrasonic sensors, two integrated in the front bumper and two integrated in the rear bumper, measure the distance to an obstruction. Obstructions detected by the sensors are tracked along the side of the vehicle as it moves. They are shown on the central information display and, in situations where a collision is imminent, an acoustic warning also sounds.
Obstructions approaching the stationary vehicle are not taken into account, as in this case the system cannot evaluate the situation unequivocally. The prerequisite for identifying obstructions is that the (driver's) vehicle is moving.

The distance markings shown on the central information display are displayed for approximately 13 seconds once the vehicle has stopped. The markings are only shown again once the vehicle starts moving.

18.7. Operation

There are two ways to activate the Parking Maneuver Assistant function:

- Activation via parking assistance button
- Activation by "Engaging reverse gear" followed by "iDrive controller operation"

Activation via parking assistance button

When the PMA is activated via the parking assistance button in the center console the parking assistance menu in the Central Information Display CID is displayed. As soon as a parking space is found, the driver receives handling instructions that guide him through the parking procedure with the support of the system. When parking automatically, the driver must hold down the parking assistance button until the parking procedure is complete.
Activation by "Engaging reverse gear" followed by "iDrive controller operation"

When reverse gear is engaged, the Parking Maneuver Assistant menu is displayed on the central information display accompanied by the status of the parking space search. The Parking Maneuver Assistant (PMA) is however not yet activated. This is indicated to the driver by the Parking Maneuver Assistant symbol in the toolbar of the central information display. In order to park supported by the system, the parking operation must be activated via the controller by selecting the corresponding symbol in the symbol bar at the Central Information Display (CID). When parking automatically, the driver must hold down the parking assistance button until the parking procedure is complete.

18.7.1. Parking procedure (parallel parking)

A check mark then appears on the right below the Parking Maneuver Assistant symbol on the central information display to tell the driver that Parking Maneuver Assistant is active.

If the Parking Maneuver Assistant function is activated during the journey using the parking assistance button, the driver is informed about the parking space search on the CID. When a parking space is found, it appears on the corresponding page on the central information display. The driver is also instructed to stop the vehicle at the same time.
G12 Driver Assistance Systems

18. Parking Maneuver Assistant

The driver is instructed to confirm the parking space by using the turn indicator corresponding to the parking direction.

The parking procedure can now be started by pressing the parking assistance button. The parking assistance button must be held down. Then the driver must release the brake.

The button must be held down continuously until the parking procedure is complete.
Upon completion, an acoustic signal sounds and a confirmation message appears to tell the driver that the parking procedure is complete. The Parking Maneuver Assistant engages "P" thus preventing the vehicle from rolling away.

**18.7.2. Parking procedure (bay parking)**

The following graphics show the bay parking process.
G12 parking procedure using PMA (bay parking)
18.7.3. Deactivation criteria

Manual deactivation criteria

The Parking Maneuver Assistant PMA can be deactivated at any time if necessary by the driver via the controller by selecting the corresponding symbol in the symbol bar on the Central Information Display CID. Another way to deactivate the Parking Maneuver Assistant PMA is to release the parking assistance button in the switch block next to the iDrive controller.

If a fault develops, a Check Control message ("The PDC has malfunctioned. Have system checked.") is displayed in the Central Information Display CID.

Automatic deactivation criteria

The Parking Maneuver Assistant PMA is switched off automatically when the following events occur:

- the parking assistance button is released
- the driver holds on to the steering wheel or steers himself
- a gear is selected that does not correspond to the instruction on the control display
- when accelerating
- the parking brake is secured
- the turn indicator opposite the required parking side is switched on
- at speeds above about 10 km/h
- possibly if the roadway is covered with snow or is slippery
- the tailgate is open
- possibly if the objects are difficult to overcome, e.g. curbs
- if obstructions suddenly appear
- a maximum number of parking maneuvers or the parking duration has been exceeded.

18.8. Limits of the system

The detection of objects can test the ultrasonic measurement system to its limits. Several examples of this are shown below:

- with trailer towbars and couplings
- if the objects are thin or wedge-shaped
- if the objects are projecting and elevated, e.g. wall projections or loads
- if the objects have corners and sharp edges
- if the objects have fine surfaces or structures, e.g. fences.

Low objects that are already displayed, e.g. curbs, may fall within the blind spot of the sensors before or after a continuous alarm sounds. It would not be possible to detect objects that are higher up and projecting, e.g. wall projections. Parking spaces may be detected although these are not suitable.
G12 Driver Assistance Systems

18. Parking Maneuver Assistant

There may be other functional limitations in the following situations, for example:

- if the sensors are soiled or iced up
- in heavy fog, rain or snow
- on uneven surfaces, e.g. gravel roads
- on slippery surfaces
- on steep inclines or downhill gradients
- if leaves have gathered or snow has piled up in the parking space.

To ensure the ultrasonic sensors remain fully operational, they must be kept clean and free of ice. When cleaning the sensors using a high pressure cleaner, avoid direct and sustained contact with a high-pressure water jet. Furthermore, when using high pressure cleaners, a distance of at least 30 cm from the sensors must be maintained.

⚠️ The Parking Maneuver Assistant PMA cannot replace the driver’s personal judgement of the traffic situation. Also check the traffic situation around the vehicle by looking around, otherwise there may be a risk of an accident as a result of road users or objects which lie outside the detection range of the Park Distance Control. Loud sound sources outside and inside the vehicle may mask the acoustic signals of the Parking Maneuver Assistant PMA or the Park Distance Control PDC.
19. Cruise Control

19.1. Introduction

Two cruise control functions can be used in the G12. The cruise control with braking function (DCC) is part of the basic equipment.

The customer also has the option of ordering the Active Cruise Control with Stop&Go function (ACC Stop&Go) optional equipment (OE ZN7) part of ZDT Driver Assistance Plus II.

ACC Stop&Go can also be obtained if the customer opts for the Active Driving Assistant Plus optional equipment (OE 5AT), as it is contained in this equipment package.

Other features of the Active Driving Assistant Plus optional equipment (OE 5AT) are the steering and lane control assistant and the traffic jam assistant. When used in conjunction with the steering and lane control assistant and the traffic jam assistant, ACC Stop & Go provides optimum support for the driver.

The cruise control systems support the driver with adapting the speed, distance and driving style to the traffic conditions, but do not relieve him of his responsibility. The driver must actively intervene, e.g. by braking, steering or taking evasive action, as otherwise there is a risk of an accident.

19.2. Cruise control with braking function

The cruise control with braking function is included as part of the G12's basic equipment. The system is also known as "Dynamic Cruise Control" (DCC). Dynamic Cruise Control (DCC) supports the driver on roads with less traffic by keeping the speed constant irrespective of rolling resistances (incline, downhill driving and vehicle load). In spite of the support, the driver remains responsible for control of the vehicle. It is possible to override the DCC function at any time by braking or accelerating the vehicle.

19.2.1. Control functions

Cruise control

The cruise control calculates a target acceleration or deceleration based on the speed set by the driver and the actual speed.

Acceleration and deceleration

The driver can specify the set speed or acceleration via the rocker switch on the multifunction steering wheel (MFL).

Cruise control on bends

Another purpose of this function, also referred to as the "lateral acceleration controller", is to prevent the lateral acceleration from increasing above an acceptable level when cornering with the cruise control switched on. A lateral acceleration is calculated from the driving speed and yaw rate. This value is compared with a speed-dependent limit in order to achieve the following seemingly contradictory objectives:
G12 Driver Assistance Systems

19. Cruise Control

- Disruptive and overly restrictive interventions are avoided if the driver himself would also prefer high lateral acceleration.
- Useful interventions and therefore also significant limitations in dynamics are effected at high speeds. Most drivers find an overly high lateral acceleration in these situations unpleasant, which is why a lower limit value is used.

The output variable for the cornering cruise control is also used as a set-point value for the longitudinal acceleration.

Prioritization of the partial set-point value

The set-point value with the highest priority according to the situation is selected from the longitudinal acceleration set-point values for the control functions referred to above. Signals are filtered to prevent abrupt jumps when adjusting the set-point values.

Estimation of disturbance force

An acceleration or brake force must be calculated in order to be able to apply the prioritized longitudinal acceleration with the assistance of the actuators. Example: more driving power is required to achieve the same longitudinal acceleration during an uphill journey than on the flat. If the vehicle needs to decelerate when travelling up hill, less braking force is required compared to driving on the flat. In order to be able to correctly calculate the forces required, the precise value of the gradient and also the weight of the vehicle, the rolling resistance, the drag and other acceleration forces must be known. As a sensor system that can monitor all of these disturbances does not exist, an estimated value is calculated instead by comparing the following two variables:

- actual movement variables of the vehicle
- anticipated movement variables of the vehicle as a result of the driving power and braking forces currently acting on the vehicle.

The extent of the disturbing force determined using this method is taken into account during subsequent processing of the longitudinal acceleration setpoint value by means of addition or subtraction.

19.2.2. Activation of the actuators

Driving power and/or braking forces must be introduced in order to produce the longitudinal acceleration calculated by the control functions and thus compensate for disturbing forces acting on the vehicle. To accelerate the vehicle, a setpoint value for the drive is usually transmitted. In exceptional cases during downhill driving on a steep gradient, it may be necessary to activate the brake to ensure the acceleration does not exceed a specific value.

If the vehicle needs to be decelerated, the extent of the contribution that may be required by the drive towards the deceleration, and therefore the braking effect of the engine and transmission, is initially determined. This value is output to the Digital Motor Electronics (DME) or and electronic transmission control (EGS). If this value cannot be achieved by the drivetrain alone, the additional amount required is transmitted to the Dynamic Stability Control (DSC).

The vehicle's brake lights are also switched on if the brakes are noticeably actuated in order to produce the desired deceleration.
19.2.3. Operation

The driver has the option of adjusting the set speed in small or large increments, which is then set and maintained by the system by controlling the drive and brakes. It can be changed using the left-hand switch block on the multifunction steering wheel (MFL). The speed is increased or reduced by 1 km/h by tapping the rocker switch. Each time the rocker button is pressed beyond the pressure point, the speed increases or reduces by 10 km/h. The DCC steadily maintains a selected speed from about 30 km/h.

The set speed is indicated in the instrument cluster KOMBI in the familiar way; by a mark that moves round the speed reading. Notes are added to the displays in the instrument cluster if necessary.

If the vehicle’s own deceleration is not sufficient to maintain the preset speed, the brake is activated accordingly.

The adjustment range for the set speed is limited to a maximum of 210 km/h.

If ECO PRO or SPORT mode is activated, the cruise control is also set to a fuel-efficient or sporty driving style. Due to the fuel-efficient driving style in ECO PRO driving mode, in some situations the vehicle’s speed may exceed or drop below the set speed, for example on downhill gradients or inclines.

G12 Driver Assistance Systems

19. Cruise Control

The system is interrupted automatically in the following situations:

- If the brakes are used
- If the selector lever position is moved out of position "D"
- If the Dynamic Traction Control (DTC) is activated or the Dynamic Stability Control (DSC) is deactivated
- If the Dynamic Stability Control (DSC) is performing an adjustment

19.3. Active cruise control with Stop&Go function

The active cruise control with Stop&Go function, ACC Stop&Go (OE 5DF) is offered as optional equipment for the G12 as part of the ZDB Driver Assistance Plus II (5AT) package.

ACC Stop&Go adjusts a driver-specified set speed and, if required by the traffic situation, also automatically adjusts the preselected following distance to the vehicle driving ahead (detected vehicles include passenger cars, trucks and motorbikes). The application range of ACC Stop&Go ranges from higher speeds down to a standstill. The distance and the speed are automatically adjusted in this range.

Depending on the stationary time, driving off from a standstill is performed automatically or in response to a prompt by the driver. ACC Stop&Go not only detects vehicles that are slowly coming to a halt, but also stationary vehicles.

Due to improved monitoring in front of the vehicle, the system is capable of reacting more quickly to vehicles swinging in and out and turning off.

The extended application range has been achieved by the incorporation of the KAFAS stereo camera. Image data is evaluated by the ACC Stop&Go system. The KAFAS control unit clearly detects vehicles when their rear ends are recorded by the camera. In addition, the KAFAS control unit ensures that the driving lane information, vehicle positions and movements are determined.

In addition to image data, radar data is also gathered and evaluated by the radar sensors. This fusion of image and radar data makes possible the clear identification of lane markings and the distinction between stationary vehicles and other fixed objects.
Object detection provided by a combination of radar sensor and KAFAS stereo camera

A 77 GHz radar sensor emits bundled electromagnetic waves. The echoes reflected by objects are received and evaluated by the radar sensor. This enables information about objects located in front of the radar sensor to be obtained. This information includes size, distance and the deduced speed. The radar sensor of the system can identify vehicles ahead up to a distance of 200 m, to a large extent irrespective of weather conditions.

The sensor is located behind the air inlet grille on the front bumper.

Index | Explanation
--- | ---
1 | Adjustment feature
G12 Driver Assistance Systems

19. Cruise Control

Thanks to the radar sensor's improved detection capability and alignment with the image data from the KAFAS stereo camera, vehicles in neighboring lanes are also detected. If these vehicles are driving in their own lane, then ACC Stop&Go adapts the speed to the vehicle pulling in or vehicle ahead. As a result, a time lag selected by the driver is constantly maintained.

ACC Stop&Go adjusts the speed if there is no vehicle driving directly ahead and automatically switches to distance control if the sensor system detects a slower vehicle in its lane. The system's Stop & Go function brings the vehicle to a complete standstill if necessary.

⚠️

If the vehicle ahead drives off again after a standstill, the driver is informed thereof with a note. To drive off again, the driver must acknowledge this information by pressing the RES/CNCL button or the accelerator pedal. Only if the duration of the standstill is very short (about 3 seconds) is the starting process effected fully automatically by ACC Stop&Go.

In this way, ACC Stop & Go supports the driver not only in flowing traffic, but also in traffic jam situations, both on multiple-lane highways and ordinary roads and on urban arterial and ring roads.

The adjustment range for the set speed is limited to a maximum of 210 km/h.

If ECO PRO or SPORT mode is activated, the Active Cruise Control with Stop&Go function is also set to a fuel-efficient or sporty driving style. Due to the fuel-efficient driving style in ECO PRO driving mode, in some situations the vehicle's speed may exceed or drop below the set speed, for example on downhill gradients or inclines.

19.3.1. Control functions

The calculations are performed in the optional equipment control unit SAS.

Cruise control

In principle, the cruise control in the ACC Stop&Go system works in exactly the same way as the Dynamic Cruise Control (DCC) system.

Cruise control on bends

The cruise control of the ACC Stop&Go on bends is based on the control characteristics of the Dynamic Cruise Control (DCC). If an object is lost on bends, the system waits to see whether the object reappears (transition curve). The vehicle only accelerates if it does not reappear or the sensor system no longer detects an object. Tight bends are detected via the data of the Dynamic Stability Control system DSC and the navigation system and the speed adjusted if necessary.

Distance control (ranging)

The distance control is the core function of the ACC Stop&Go system.

The driver can select a desired distance in four stages using the multifunction button on the multifunction steering wheel (MFL). From this preselection ACC Stop&Go calculates the reference distance to the vehicle driving ahead for the control. In vehicles with the Active Cruise Control optional
**G12 Driver Assistance Systems**

**19. Cruise Control**

equipment (OE 5DF), the distance is adjusted using two buttons; one to reduce and one to increase the distance. In vehicles with the Driving Assistant Plus optional equipment (OE 5AT), the distance is adjusted using the rocker button.

ACC Stop&Go calculates the reference distance for the control from this preselection. The following distance most recently selected is saved depending on the key being used.

The reference distance during the journey is proportional to the driving speed. At a lower driving speed and at standstill, the proportional distance to the driving speed is no longer used for the ACC Stop & Go, but a fixed value in metres.

If a vehicle moves into the driver's lane, which is anticipated due to the current driving condition, or if the driver is approaching a vehicle driving ahead, the ACC Stop&Go function discretely adapts the speed to the vehicle pulling in or vehicle ahead.

The distance control uses the prepared object data with the highest diagnostic statistic as input variables. The distance control takes into consideration the following situations in particular:

- **Maximum values for acceleration and deceleration:**
  The maximum values for acceleration and deceleration of the ACC Stop&Go system below about 50 km/h are dynamic values. They correspond to the acceleration and deceleration values that the driver would use himself and considers comfortable. In situations where sharper deceleration is required than the system offers as part of the speed adjustment feature, a visual and acoustic signal is issued to the driver to inform him to take over vehicle handling.
  Depending on the situation, the ACC Stop & Go accelerates by a maximum of about 2 m/s² and decelerates by a maximum of about 4 m/s².

- **Stop and start stability:**
  In the case of very heavy traffic and very low driving speed, the risk of rear-end collisions increases through heavy acceleration and braking. The ACC Stop&Go distance controller is therefore designed to decelerate as early as possible, but not more than the vehicle ahead.
  The system can decelerate by up to 2.5 m/s² at the most during subsequent operation, and by up to 4 m/s² at the most when stopping.

**Request to take over vehicle handling**

When ACC Stop&Go is no longer able to maintain a safe distance or a critical situation is detected, e.g. on account of very high differential speeds or an insufficient maximum deceleration, two short warning signals sound and the orange lit up vehicle symbol in the instrument cluster or the Head-Up Display (optional equipment OE 610) flashes. The system continues to perform its control function and prompts the driver to take over vehicle handling and to keep their distance accordingly.

**19.3.2. Operation**

**Activation and deactivation**

The activation and deactivation of the ACC Stop & Go and the Dynamic Cruise Control are almost the same. ACC Stop&Go can either be activated while driving or at a standstill. For safety reasons, when the vehicle is at a standstill the function can only be put in Standby mode or deactivated while the footbrake is applied.
G12 Driver Assistance Systems

19. Cruise Control

If the function is active, it can be interrupted by pressing the RES/CNCL button. The distance and speed will no longer be maintained and the set speed is greyed out in the instrument cluster.

The driver can select a desired distance in four stages using the left-hand multifunction button on the multifunction steering wheel (MFL). The last selected following distance is saved depending on the key being used.

- The following graphic shows the button assignment for the assistance systems on the multifunction steering wheel (MFL) in vehicles with the Active lane keeping assistant including traffic jam assistant:

<table>

</tr>
</tbody>
</table>

The following conditions must also be satisfied for activation:

- Seat belt fastened and doors closed
- Drive position "D" engaged and brake pressed
- Engine running
- Parking brake not activated
- Camera and radar sensor operational
- No system faults detected.
G12 Driver Assistance Systems

19. Cruise Control

The system is interrupted automatically in the following situations:

- If the brakes are used
- If the selector lever position is moved out of position "D"
- If the Dynamic Traction Control (DTC) is activated or the Dynamic Stability Control (DSC) is deactivated
- If the Dynamic Stability Control (DSC) is performing an adjustment
- If the seat belt is unfastened and the driver's door is opened in a stationary vehicle
- If the system has not detected an object for a long time, e.g. on rarely frequented sections of road with no distinct edge
- If the detection range of the radar is impaired, e.g. due to contamination or heavy precipitation
- Following a longer immobilization period, if the vehicle has been decelerated to a standstill by ACC Stop&Go.

The set speed is indicated in the instrument cluster in the familiar way; by a mark that moves round the speed reading. If ACC Stop&Go is activated, this mark is green, whereas in "Standby" mode it is grey and the last set speed is displayed. After the ACC Stop&Go function is activated or after the driver has adjusted the set speed, the current digital value is displayed. If the distance is changed, a symbol appears briefly as an acknowledgement. The symbol screen masks are for example the set speed and the distance bar. With each subsequent operation the display is shown for another three seconds.

The distances set by the driver, as well as the distances to any vehicles driving ahead, that must be maintained to ensure a safe distance are displayed between the two round instruments (speed reading and engine speed display). The distance setting is stored for the ID transmitter currently being used. Like for DCC, it is also necessary that the symbol screen masks are complemented if necessary with notes in the instrument cluster for ACC Stop & Go.

With active control the displays are also shown in the Head-Up Display (optional equipment OE 610).

If the system can no longer adjust a safe distance, for example due to very high differential speeds, then the driver is prompted to take over the vehicle handling by a flashing red vehicle symbol and an acoustic signal.

G12 Driver Assistance Systems

20. Speed Limit Warning

The driver has the option of setting a speed at which a warning is issued when the system is activated and the preset speed is exceeded.

20.1. Operation

The speed limit warning can be switched on and off in the iDrive menu, as well as the speed setting at which the warning should be issued, by making the following selection via the controller:

- "My Vehicle"
- "Vehicle settings"
- "Speed limit warning"
- "Warning at:"
- turn controller until the desired speed is displayed
- press controller
- speed limit warning is saved.

![Speed limit warning display on the CID](image)
G12 Driver Assistance Systems

21. Lateral Guidance Assistants

This increased the speed range in which the system can be used from 40 km/h to 60 km/h.

The below graphic shows when the lateral guidance systems were introduced:

<table>
<thead>
<tr>
<th>Index</th>
<th>System</th>
<th>Functional characteristics of the systems</th>
</tr>
</thead>
</table>
| 3     | Traffic jam assistant (from 2015 with launch of G12) | • 0 - 70 km/h

• Lane center guidance  
• No road-type restrictions |
| 4     | Active lane keeping assistant with active side collision protection (from 2015 with launch of G12) | • 30 - 70 km/h (warning in form of single steering wheel pulse)  
• 70 - 210 km/h (corrective steering interventions)  
• Active steering interventions in situations where a collision is imminent  
• No road-type restrictions |

The steering and lane control assistant and active lane keeping assistant with active side collision protection have been introduced for the first time in the G12.
The lane keeping assistant with traffic jam assistant is part of the Active Driving Assistant Plus optional equipment (OE 5AT).

The system assists the driver in keeping the vehicle in lane by initiating corrective steering interventions if required.

22.1. Functional principle

Depending on the speed, the system is guided by the lane edges or vehicles driving ahead. The position of the lane edges and the vehicle driving ahead is determined with the help of five radar sensors and the KAFAS stereo camera.
G12 Driver Assistance Systems
22. Lane & Traffic Jam Assistant

</tr>
</tbody>
</table>
G12 Driver Assistance Systems

22. Lane & Traffic Jam Assistant

The system has two sub-functions: the traffic jam assistant (second generation) and the lane control assistant.

The traffic jam assistant can be used within the speed range of 0 to 70 km/h, the lane control assistant on the other hand from 70 to 210 km/h.

The table below shows an overview of the differences between the two sub-functions:

<table>
<thead>
<tr>
<th>Traffic Jam Assist</th>
<th>Lane Control Assistant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Speed range 0 - 70 km/h</td>
<td>Speed range 70 - 210 km/h</td>

<td>lane</td>
</tr>
<tr>
<td>Detected lane markings taken into</td>
<td>Gaps in lane markings can be bridged for a limited time by aligning</td>
</tr>
<tr>
<td>consideration</td>
<td>with vehicle ahead</td>
</tr>
</tbody>
</table>

If the traffic jam and lane control assistants are activated, the side collision warning is also interlinked.

22.1.1. Hands-off-Detection

To ensure the driver is alert and able to react, he is urged to always have both hands on the steering wheel when the steering and lane control assistant including traffic jam assistant are activated (established in the German road traffic regulations). If the driver takes both hands off the steering wheel rim, control is stopped after a few seconds during active control and the driver is requested to take over steering.

A capacitive sensor (hands-off detection sensor) with corresponding touch detection electronics in the steering wheel determines whether the steering wheel is being touched.

The electronic touch detection is installed in the steering wheel below the driver's airbag.
The hands can only be detected on the steering wheel rim, not on the steering wheel spokes, hub or impact plate.

The sensor consists of a mat which is wrapped round the steering wheel rim.
The lane keeping assistant with traffic jam assistant is deactivated a few seconds after a hand is no longer touching the steering wheel rim. In order to be able to use the steering and lane control assistant including traffic jam assistant, the steering wheel must be grasped. When driving with gloves on or with a steering wheel cover fitted, the sensor may not be able to detect contact with the steering wheel, which means the system may not be able to be used.

The diagnosis of the Hands-off-Detection is performed in the Body Domain Controller BDC.

**22.1.2. Functional prerequisites**

The following prerequisites must be met in order for the steering and lane control assistant including traffic jam assistant to be used:
G12 Driver Assistance Systems

22. Lane & Traffic Jam Assistant

- Speed must be below 210 km/h.
- Above 70 km/h: both lane edges must be detected.
- Below 70 km/h: both lane edges or a vehicle driving ahead must be detected.
- The lane width must be sufficient.
- The vehicle should be positioned as centrally as possible in the lane.
- There must be a sufficient curve radius.
- At least one hand must be on the steering wheel rim.
- The turn indicator must not be activated.
- The camera calibration process must be completed immediately after vehicle delivery.

The active lateral control function with data evaluation of the KAFAS stereo camera is implemented with the assistance of the lane markings identified on the left and right.

In order for the system to be activated, two lane boundary lines must be detected. Below a speed of approximately 70 km/h a vehicle driving ahead in the same lane is sufficient to activate the system.

The system is put in Standby mode if the marginal conditions are not satisfied (e.g. hands not on steering wheel, lane too narrow or dazzling of KAFAS stereo camera). Once all marginal conditions have been met, the system is re-enabled automatically.

To activate the system, the speed of the vehicle is another input quantity that is evaluated. The system uses these values to decide which function is enabled. As mentioned above, the threshold values are set as follows:

- The traffic jam assistant can be enabled within a speed range of 0 to 70 km/h.
- The lane control assistant can be enabled within a speed range of 70 to 210 km/h.

22.1.3. Lane change

For a lane change to be as comfortable as possible, the steering and lane control assistant including traffic jam assistant is put silently into Standby mode when the turn indicator is activated and reactivates itself automatically once the turn indicator is back in its initial position and a lane change has occurred.

22.1.4. Function logic

The main function logic of the lateral guidance is implemented in the optional equipment system (SAS) control unit.

The majority of the data for the function is provided by the KAFAS stereo camera, where algorithms for the lane and object detection run.

Vehicle dynamics data, such as the driving speed, wheel speeds, yaw rate, steering angle, lateral acceleration, longitudinal acceleration, etc., is provided by the rest of the vehicle network via a FlexRay or CAN connection.

A target trajectory (also known as a path curve) is calculated in the optional equipment system (SAS) control unit. This is used to determine whether a steering correction is required.
22.1.5. Steering interventions

If the current course of the vehicle deviates too much from the target trajectory (path curve), a steering correction is initiated.

The steering intervention is a corrective measure. This means the driver is not relieved of his duty to steer the vehicle. As the corrective steering interventions are limited to approximately 1.5 m/s² based on the lateral acceleration, the system cannot navigate curves above the respective speed-dependent curve radius without the driver's assistance. The driver must therefore steer the vehicle at the same time in order to stay on the roadway.

The target trajectory and required steering corrections are calculated based on the driving speed as follows:

**Speed range 0 to 70 km/h:**

- The position and previous movements of the vehicle driving ahead are given priority when determining the appropriate steering corrections.
- Detected lane markings are taken into account to avoid unwanted steering corrections that would result in leaving the lane.
- Corrective steering interventions in the direction of the center of the lane are initiated if the vehicle detects there is not a vehicle driving ahead.

**Speed range 70 to 130 km/h:**

- Corrective steering interventions in the direction of the center of the lane are initiated.
- It is possible to bridge the gap for a limited time where lane markings are not detected by estimating the course of the lane based on the vehicle driving ahead.

**Speed range 130 to 210 km/h:**

- Corrective steering interventions in the direction of the center of the lane are initiated.
- For safety reasons above a driving speed of approximately 130 km/h the course of the lane is not estimated using the vehicle driving ahead.

The vehicle driving ahead is given priority as the "correction target" at speeds ranging between approximately 0 and 70 km/h due to the limited detection of lane markings.

In traffic jams or slow-moving traffic following distances are often extremely small (< 10 m) due to tailgating and lanes ahead are often partially covered due to staggered driving.

This means the KAFAS stereo camera is unable to correctly interpret the lane markings in some cases.

When classifying the object driving ahead, vehicles such as motorbikes are not used as the "correction target".

**Steering torque**

The driving dynamics function software in the Dynamic Stability Control (DSC) control unit calculates a target steering torque based on the curve nominal value. The target steering torque is then converted to an engine torque by the Electronic Power Steering (EPS), which finally results in a steering wheel movement at the wheels.
The maximum steering torque has been set in such a way that it can always be overruled by the driver and therefore steering past the maximum steering torque is possible.

22.1.6. Operation

The system is switched on via the traffic jam assistant button on the multifunction steering wheel (MFL).

22.1.8. Deactivation criteria

The steering and lane control assistant including traffic jam assistant is deactivated automatically in the following situations:

• If the vehicle departs from the detected lane or the lane width does not meet the requirements.
• If the lane edges of the current lane are not detected by the KAFAS stereo camera.
• If no vehicle driving ahead is detected.
• The vehicle is travelling at a speed greater than 210 km/h.
• If the Hands-off-Detection cannot detect the hands (at least one hand) on the steering wheel rim. Switch-off occurs once a defined time threshold (several seconds) has elapsed.
• Due to the radius of the bend in the road, the inner lane edge is no longer detected due to the camera aperture angle.
• Pedestrian protection assumes the operating condition "Fault exists".
• If the turn indicator is on.
• The driver intervenes actively in the steering.
• If over a certain time period no lane edges are detected and there is not a vehicle driving ahead.
  • If the driver manually deactivates the DSC (DSC off).
  • If there is an intervention from the preventative pedestrian protection.
• After Dynamic Brake Control braking (brake assistant).

22.1.9. Limits of the system

When driving in narrow lanes, e.g. when driving through roadworks or when emergency lanes are formed, the system cannot be activated or used meaningfully.

⚠️

Due to the limited detection capacity of the KAFAS stereo camera, the driver must remain alert and observant in order to be able to actively intervene at any time so as to avoid the risk of an accident. The system does not relieve the driver of personal responsibility for correctly judging the traffic situation. The driver is solely responsible for the vehicle.
The active lane keeping assistant with active side collision protection is part of the Active Driving Assistant Plus optional equipment (OE 5AT).

The system assists the driver in keeping the vehicle in lane and actively avoiding potential side collisions by initiating corrective steering interventions within a speed range from 70 km/h to 210 km/h. The system endeavours to orient the vehicle in its lane according to the situation and within the framework of the system limits.

The system consists of the following four sub-functions:

- Side collision warning
- Lane departure warning
- Blind Spot Detection

### 23.1. Side collision warning

The table below shows an overview of the functional characteristics of the "Side collision warning" sub-function:

<table>
<thead>
<tr>
<th>Speed range</th>
<th>Warning functions</th>
<th>Corrective steering intervention</th>
</tr>
</thead>
</table>
| 70 - 210 km/h| • Issued if the vehicle detects that it is getting critically close to another vehicle to the side  
• Physical warning in the form of vibration in the steering wheel using an unbalanced actuator  
• Visual warning in exterior mirror in the form of the corresponding warning light | • Corrective steering intervention in the direction of the available space on the roadway  
Requirements:  
• Detected lanes  
• Sufficient available space on the roadway |

### 23.1.1. Reduced side collision warning

The reduced side collision warning comes into play if it is not possible to adequately monitor the available space on the roadway or there is no available space on the roadway.

The reduced side collision warning is interlinked with the steering and lane control assistant including traffic jam assistant function.

The table below shows an overview of the functional characteristics of the "Reduced side collision warning" sub-function:
23. Active Lane Keeping Assistant

<table>
<thead>
<tr>
<th>Speed range</th>
<th>Warning function</th>
<th>Corrective steering intervention</th>
</tr>
</thead>
</table>
| 30 - 210 km/h| • Issued if the vehicle detects that it is getting critically close to another vehicle to the side  
  • Physical warning in the form of vibration in the steering wheel using an unbalanced actuator  
  • Visual warning in exterior mirror in the form of the corresponding warning light  
  • 30 - 70 km/h additional warning issued by single steering wheel pulse | • A corrective steering intervention is **not** initiated; instead only a single steering wheel pulse warning is issued in the opposite direction to the detected object the vehicle could collide with |

23.2. Lane departure warning

The table below shows an overview of the functional characteristics of the "Lane departure warning" sub-function:

<table>
<thead>
<tr>
<th>Speed range</th>
<th>Warning function</th>
<th>Corrective steering intervention</th>
</tr>
</thead>
</table>
| 70 - 210 km/h| • Triggered in the event a lane departure is detected by the lane departure warning function. The associated physical warning in the form of a vibration in the steering wheel using an unbalanced actuator is issued and visual warning in the exterior mirror in the form of the corresponding warning light. | • Corrective steering intervention in the direction of the original lane if vehicle moves towards neighboring lane  
  **Requirements:**  
  • Detected lanes |
23. Active Lane Keeping Assistant

23.3. Blind spot detection

The table below shows an overview of the functional characteristics of the "Blind spot detection" sub-function:

<table>
<thead>
<tr>
<th>Speed range</th>
<th>Warning function</th>
<th>Corrective steering intervention</th>
</tr>
</thead>
<tbody>
<tr>
<td>70 - 210 km/h</td>
<td>• Triggered in the event a lane change that could result in a collision is detected by the lane departure warning function. The associated physical warning in the form of a vibration in the steering wheel using an unbalanced actuator is issued and visual warning in the exterior mirror in the form of the corresponding warning light.</td>
<td>• Corrective steering intervention in the direction of the available space on the roadway when lane change intention is made and neighboring lane is obstructed. Prerequisites: • Detected lanes • Sufficient available space on the roadway</td>
</tr>
</tbody>
</table>

Further information can be found in the system descriptions of the respective sub-functions (see sections 8-10).

⚠️

The active lane keeping assistant with active side collision protection does not relieve the driver of his overall responsibility for driving the vehicle. Due to the system limits be attentive in order to be able to actively intervene at any time. Otherwise, there is a risk of an accident.
